Vorwort.

Das Jahrbuch für 1882 enthält die vollständigen Beobachtungen für dieselben 12 Stationen und die Uebersichtstabellen für dieselben 39 Stationen, wie der vorhergehende Jahrgang.

In Bezug auf die Lage der Stationen, die Instrumente u. s. w. ist auf die Jahrbücher für 1875 bis 80 zu verweisen. Bei den einzelnen Stationen ist folgendes zu bemerken:

Andenes. Im Januar, Februar und März ist die Minimumtemperatur nicht beobachtet. Die niedrigsten Temperaturen sind nach den gewöhnlichen Beobachtungen angegeben.

Brönö. Das Minimumthermometer wurde mehrfach durch Stürme in Unordnung gebracht. Für Januar und Februar sind die Monatsmittel der Temperatur durch Vergleichung mit Prestö berechnet. Das mittlere Minimum des März ist mit Hülfe der Beobachtungen in Prestö corrigirt worden.

Dommesten stellte seine Beobachtungen mit dem August 1882 ein.

Granheim. Die Seehöhe ist nach den Barometerbeobachtungen der Station und synoptischen Karten auf 394.^{m}7 berechnet worden Die früher benutzte Seehöhe, 381.^{m}2, welche durch Nivellement mit der Wasserwege gefunden war, ist offenbar zu klein.

Oxö. Die Station wurde am 26. October, am Nachmittag, in die Wohnung des Beobachters verlegt. Ein neues Kew-Stationsbarometer, Adie No. 1567, wurde in einer Seehöhe von 11.^{m}3 aufgestellt. Seine constante Correction ist —0.^{mm}29. In den Uebersichtstabellen, Seite 78, sind sämtliche Barometerhöhen für 1882 auf die Seehöhe 14.^{m}7 reducirt.

Tönset. Die Station wurde d. 12. Februar 1882 in das neue Haus des Beobachters in der Nähe der Eisenbahnstation verlegt. Die Seehöhe des Barometers ist hier 492.^{m}7. Die Barometerbeobachtungen der Uebersichtstabelle, Seite 74, sind für sämtliche Monate des Jahres 1882 auf diese neue Seehöhe reducirt. (Siehe Druckfehlerverzeichniss).

Im Sommer 1883 fand Inspection statt auf den Stationen Tromsö, Alten, Vardö und Südvaranger mit dem Resultat, dass die auf Seite II dieses Jahrbuches angegebenen constanten Correctionen der Barometer für das Jahr 1882 keiner weiteren Berichtigung bedürftig gefunden wurden.

Die folgende Tabelle giebt eine Uebersicht über die Lage der Stationen, die Höhe der Instrumente, die constante Correction der Barometer, die Beobachtungszeiten und die verschiedenen Beobachter. An den Telegraphenstationen ist ein bestimmter Beamter für die Beobachtungen verantwortlich. Auf den Leuchtthürmen werden die Beobachtungen vom betreffenden Leuchtfeuerverwalter ausgeführt.

Wegen der Controlle der Barometer- und Thermometerbeobachtungen siehe Jahrbuch für 1877, Vorwort Seite V.

Um das richtige Mass für den Druck der Luft darzustellen, muss die beobachtete Barometerhöhe, ausser der Reduction auf 0^0 und Normalbarometer, noch einer Reduction auf die normale Schwere (die Schwere bei 45^0 an der Meeresfläche) unterworfen werden. Wenn $G_{\varphi H}$ die Schwere an einem Ort, dessen Breite durch φ und dessen Höhe über dem Meere durch H angegeben wird, und G_{45} die normale Schwere bezeichnen, so ist nach Dr. *O. J. Broch* „Accélération de la pesanteur sous différentes latitudes et à différentes altitudes“ [1]). Seite A 9:

$$\frac{G_{\varphi H}}{G_{45}} = (1 - 0.00259 \cos 2\varphi)\,(1 - 0.000000196\, H)$$

oder, der Kürze wegen,

$$\frac{G_{\varphi H}}{G_{45}} = 1 - \alpha \cos 2\varphi - \beta H.$$

Bedeutet nun b die auf 0^0 und das Normalbarometer reducirte Barometerhöhe eines Ortes, dessen Breite φ und dessen Seehöhe H beträgt, (d. h. den Zahlenwerth der verschiedenen Barometerhöhen, wie er aus diesem Jahrbuch zu entnehmen ist,) während unter b_{45} die auf die normale Schwere reducirte Barometerhöhe zu verstehen ist, so ergiebt sich

$$\frac{b}{b_{45}} = \frac{G_{45}}{G_{\varphi H}} = \frac{1}{1 - \alpha \cos 2\varphi - \beta H},$$

und die Schwerecorrection wird somit:

$$b_{45} - b = b\,(-\alpha \cos 2\varphi - \beta H).$$

Weil die Schwerecorrection mit der jedesmaligen Barometerhöhe sich ändert, da sie ja der letzteren proportional ist, habe ich, um ihre Grösse für die einzelnen Stationen festzustellen, folgendes Verfahren benutzt. Für jede Station wurde der höchste und der niedrigste der in den Beobachtungsreihen vorkommenden Barometerstände ermittelt, und die diesen beiden Barometerhöhen entsprechenden Schwerecorrectionen berechnet. Auf ein und derselben Station variirt der Werth der Schwerecorrection bei dem höchsten und dem niedrigsten Barometerstand um nicht voll $0.^{mm}1$. Von einer Genauigkeit, die über $0.^{mm}1$ hinausgeht, kann aber bei unsern Barometerhöhen, auch abgesehen von der Unsicherheit in der constanten Correction der Instrumente, schon aus dem Grunde keine Rede sein, weil die Ablesung sich nur auf $0.^{mm}1$ erstreckt. Dazu kommt in den Fällen, wo es sich um die Reduction auf eine bestimmte Niveaufläche handelt, noch der Umstand, dass die Höhe des Barometers über dem Meeresspiegel in der Regel nur bis auf $\pm$ 1 Meter sich bestimmen lässt, da die Bestimmung des mitleren Wasserstandes mit einer so grossen Unsicherheit behaftet ist und die Abweichung des mittleren Wasserstandes von einer bestimmten Niveaufläche noch nicht durch irgendwelches Präcisionsnivellement festgestellt ist. Unter diesen Umständen lässt sich die Grösse der Schwerecorrection für jede vorkommende Barometerhöhe mit einer Genauigkeit von $0.^{mm}1$ durch 2 Zahlen angeben; man braucht nemlich nur zu kennen: die Grösse der Schwerecorrection für diejenige Barometerhöhe, bei welcher diese Correction von einem niederen Zehntel des Millimeters zum nächsthöheren überspringt. Beispiel: Für Dovre ist die Schwerecorrection $= 0.^{m}95$ bei $715.^{mm}1$. Bei Barometerhöhen über $715.^{mm}1$ ist die Schwerecorrection $+ 1.^{mm}0$, bei Barometerhöhen unter $715.^{mm}1$ ist dieselbe $+ 0.^{mm}9$. In dieser Weise ist die Grösse der Schwerecorrection im Jahrbuch für 1882 über den Tabellen sämtlicher Barometerstationen angegeben, sowohl in Abtheilung I als in Abtheilung II.

---

[1]) Travaux et memoirs du bureau international des poids et mesures, Tome I.

Die Berechnung der Barometerhöhe, bei welcher die Schwerecorrection von einem Zehntel zum nächsten überspringt, wo also in der zweiten Decimale des Millimeterbruches, welcher ihren Werth angiebt, eine Fünf erscheint, ist in folgender Weise ausgeführt:

Nennt man die respective Schwerecorrection c und die dazu gehörige Barometerhöhe b_0, so ist:

$$b_0 = \frac{c}{-\alpha \cos 2\varphi - \beta H}.$$

Aus dieser Formel findet ferner man durch Differentiation

$$d b_0 = \frac{2 b_0 \alpha \sin 2\varphi}{\alpha \cos 2\varphi + \beta H} \cdot \frac{\pi}{180} \cdot \frac{1}{60} d\varphi - \frac{b_0 \beta}{\alpha \cos 2\varphi + \beta H} d H,$$

wo b_0 in Millimetern ausgedrückt ist, $d\varphi$ in Bogenminuten und $d H$ in Metern.

Beisp.	Station.	Breite.	Höhe.	$\frac{d b_0}{d \varphi}$.	$\frac{d b_0}{d H}$.
	Mandal	58° 2′	17^m	—0.^{mm}85	0.^{mm}16
	Dovre	62° 5′	643^m	0. 72	0. 10
	Aalesund	62°29′	14^m	0. 65	0. 10
	Gjäsvär	71° 7′	7^m	0. 35	0. 07

Handelt es sich nun darum b_0 mit einer Genauigkeit von 0.^{m}05 zu bestimmen, um so jeden Zweifel über die Anzahl der für die Correction von b_0 zuverwendenden Millimeterzehntel auszuschliessen, so müsste man hier in Norwegen die Breite der Station bis auf 3 bis 9 Bogenminuten und die Höhe über dem Meeresspiegel bis auf 0.3 bis 0.7 Meter kennen; alles unter der Voraussetzung, dass die Grösse der Schwere sich nach dem angenommenen Ausdruck genau berechnen lässt.

Anm. Wie man einsehen wird, ist die Schwerecorrection leicht mit der Reduction auf 0° in einer Tabelle zu vereinigen, und es lässt sich dieselbe darum auch ohne Vermehrung der Reductionsarbeit an jeder publicirten Barometerhöhe anbringen. Dies wäre gewiss für die Meteorologen ein zuerstrebendes Ziel. Die Fehler, welche durch Ausserachtlassung der hier besprochenen Correction in die synoptischen Karten, und namentlich in die klimatischen Isobarenkarten sich einschleichen, werden desto fühlbarer, je zahlreicher und genauer die für die verschiedenen Welttheile publicirten Barometerbeobachtungen geworden sind. Was die Bestimmung der Grösse der Schwere auf den einzelnen Stationen betrifft, so dürfte das von Mascart angegebene Instrument (Annuaire de la Société météorologique de France. Juin 1883, S. 172) vielleicht Hoffnung geben auf eine Lösung dieser Aufgabe durch ein Verfahren, das practisch nicht schwererer auszuführen ist, als die Vergleichung zwischen dem Stationsbarometer und dem Reise-Normalbarometer an den verschieden Beobachtungsorten.

Die Tabellen der ersten Abtheilung enthalten:

Die Barometerhöhe in Millimetern, auf 0° reducirt und mit der constanten Correction des Instrumentes corrigirt[1]). Die beobachteten Maxima und Minima des Monats sind mit fetten Typen gedruckt.

Die Lufttemperatur nach Celsius. Die Ablesungen des Index des Minimumthermometers sind durch tägliche Vergleichung desselben mit dem trocknen Thermometer corrigirt worden. Wo die Lufttemperatur in der Nacht, zwischen 8 Uhr Abends und 8 Uhr Morgens kein Minimum nachweist, ist die Temperatur für 2 Uhr Morgens interpolirt und mit Cursiv gedruckt worden. Dies ist geschehen, damit das Mittel aus den 4 täglichen Beobachtungen,

[1]) Wegen des Normal-Barometers siehe Jahrbuch für 1874.

inclusive der interpolirten Nachttemperatur, möglichst genau die wahre 24 stündige Mitteltemperatur des Tages ergeben kann.

Die beobachteten Maxima und Minima sind mit fetten Typen gedruckt.

Den Dunstdruck in Millimetern aus den Psychrometerbeobachtungen nach Jelineks Tabellen berechnet. Die beobachteten Maxima und Minima sind mit fetten Typen gedruckt.

Die relative Feuchtigkeit auf dieselbe Weise berechnet. 00 = 100%.

Die Windrichtung rechtweisend nach 16 Strich, in den englischen Bezeichnungen ausgedrückt.

Die Windstärke nach Schätzung, Scala 0 = Still bis 6 = Orkan[1]).

Die Bewölkung nach der Scala 0 = Heiter bis 10 = Ueberzogen.

Die Höhe des Niederschlags in Millimetern, angeführt für den Tag, an welchem er gefallen ist. Der am Morgen gemessene Niederschlag ist also für den vorhergehenden Tag angeführt worden, ausgenommen in solchen Fällen, wo man mit Bestimmtheit weiss, dass er nach Mitternacht gefallen ist.

Bemerkungen über Niederschlag und andere Phänomene mit zugehöriger Tageszeit.

Die Bezeichnungen sind:

● Regen.	*n* Nacht	Als Exponent
∗ Schnee.	*a* Vormittag	
△ Graupeln.	*p* Nachmittag	
≡ Nebel.	*o* Schwach	
⌴ Reif.	*2* Stark	
∞ Höhenrauch.	1 Erste Beobachtungsstunde.	
⸝ Starker Wind.	2 Zweite —	
ꓘ Gewitter.	3 Dritte —	
< Blitz ohne Donner.		
♖ Nordlicht.		
⊕ Sonnenring.		
⦶ Sonnenhof.		
⦷ Mondring.		
⦸ Mondhof.		

Niederschlag oder andere Phänomene, die während eines der 3 festen Beobachtungsmomente wahrgenommen wurden, sind bezeichnet durch eine dem Zeichen des Phänomens nachgesetzte, die Beobachtungsstunde angebende, Ziffer: z. B. ● 1, Regen 8^h Morgens; ∗ 3, Schnee 8^h Abends. Niederschlag oder andere Phänomene, die zwischen den festen Beobachtungszeiten beobachtet wurden, sind bezeichnet durch ein dem Zeichen des Phänomens als Exponent nachgesetztes *n*, *a* oder *p*.

Interpolirte Werthe sind mit Cursiv gedruckt.

In den Uebersichtstabellen der zweiten Abtheilung sind die Luftdrucksmittel direct aus den Monatsmitteln der drei Beobachtungsstunden berechnet. Alle sind auf 0° und absoluten Stand, aber nicht auf die Meeresfläche reducirt.

Die Monatsmittel der Lufttemperatur (Celsius) sind als Mittel der drei täglichen festen Beobachtungen und der Minimum-Temperatur bestimmt.

Für Christiania sind die mittelst Maximumthermometer beobachteten absolut höchsten Temperaturen in jedem Monat mit zugehörigen Datum aufgeführt. Sonst sind es die auf die

---

[1]) Eine Vergleichung der geschätzten Windstärken mit gemessenen Windgeschwindigkeiten findet sich im Jahrbuche für 1874. Siehe auch Jahrbuch für 1875. Vorwort, Seite II.

Beobachtungsstunden fallenden Maxima, und die mittelst Minimumthermometer gefundenen Minimumtemperaturen, welche aufgeführt wurden.

Die Monatsmittel der absoluten und relativen Feuchtigkeit sind als Mittel aud den Morgen- und Abendbeobachtungen, ohne Correction berechnet. Für Dovre, Röros und Tönset ist Correction wegen des Luftdrucks an den Mitteln angebracht worden.

Die Monatsmittel der Bewölkung sind die Mittel aus den drei täglichen Beobachtungen.

Der Niederschlag ist die Monatssumme.

Die Zahl der Tage mit Niederschlag u. s. w. Tage, wo Schnee und Regen gemischt waren, sind als Schneetage gerechnet. Heitere Tage sind solche, wo die Summe der Bewölkung für alle drei Beobachtungsstunden weniger als 6 beträgt. Trübe Tage sind solche, an denen die Summe grösser ist als 24. Sturmtage sind solche, an welchen die an Wilds Windstärkeplatte beobachtete Geschwindigkeit des Windes 15 Meter überstieg, oder (an den Stationen, die keine Windmesser haben,) die Windstärke über 4 notirt ist.

Die Windvertheilung ist direct aus den notirten Beobachtungen abgeleitet.

Das Monatsmittel der Windstärke ist das Mittel aus den drei täglichen Beobachtungen.

Bei den Leuchtthurmstationen ist die Meerestemperatur das Monatsmittel für die Beobachtungsstunde 8 Uhr Morgens.

Als Anhang I sind dynamische Windrosen für 24 Stationen beigegeben. Wenn eine Windrichtung während eines Monats nicht notirt worden ist, so wird dies durch einen Strich bezeichnet. Bei der Berechnung des Jahresmittels sind die für jeden Monat und für jede Windrichtung gefundenen Summen der Windstärke zusammenaddirt, und als Divisor die Anzahl der sämtlichen für das Jahr notirten respectiven Windrichtungen benutzt, welche letztere aus dem 2. Theil des Jahrbuches „Windvertheilung: Jahr" entnommen ist.

Als Anhang II folgen Beobachtungen über die Bewegung der Cirruswolken.

Die Berechnungen für das Jahrbuch haben die Herren Assistenten *A. Steen, K. Hesselberg, N. Offedal, A. Bendixen* und *H. Chr. Löcken* ausgeführt. Die vier erstgenannten Herren sind mit der Correctur beschäftigt gewesen.

Christiania, November 1883.

H. Mohn.
