"This project was supported, in part, by Federal Coastal Zone Management Program Implementation Funds (P.L. 92583, Sec. 306) granted to the State of Alaska by the Office of Coastal Zone Management, National Oceanic and Atmospheric Administration, U.S. Department of Commerce."

ACKNOWLEDGEMENTS

I would like to express my thanks and appreciation to the following people:

Joe Yuska and Chuck Huntington, two Oregon State University graduate students, for their long, hard hours in the field, for their assistance with the data interpretation and for their invaluable advice concerning stream inventories.

The Annette Island U.S. Weather Bureau staff for the helium, the use of tools, regulators, and muscle-power, and for their instructions concerning balloon handling.

Dale Williams, for his assistance in interpreting and providing additional insight to the U.S. Fish and Wildlife Service data. Also thanks to many of the Metlakatla Indian community members who provided me with additional historic information concerning Annette Island streams and the salmon resource.

The Metlakatla Indian Community, Annette Natural Resource Center staff for their assistance in keeping this project rolling and for the use of their offices and equipment.

Pacific Rim Planner, Inc., for providing me with office space and for their advice and assistance concerning this project.

Finally, to June Hanley who put in long hours and did an excellent job typing this report.

Annette Islands Stream Survey

Evelyn Biggs, Fisheries Management Biologist

Introduction

The Metlakatla Indian Community (MIC), because of its unique right to manage the Annette Island resources, compiles a Salmon Management Plan every year. In the course of salmon fisheries management, since salmon have a freshwater life-cycle phase and since much of what happens in the streams (escapement, spawning, incubation of eggs, rearing of fry, smoltification and outmigration) determines the future magnitude of salmon stocks originating in those streams, there arises the need for a freshwater habitat evaluation. This evaluation provides baseline data for monitoring and manipulating potential and current salmon production from streams. This study was devised and compiled to provide MIC resource planners with baseline data to aid in wise management and potential enhancement of Annette Islands' valuable salmon resource.

This inventory was compiled from several previous and recent studies conducted on Annette Island. In 1971-1976, the U.S. Fish and Wildlife Service conducted stream and lake surveys on Annette Island; however, no formal report was ever published revealing these findings. In 1979, a watersheds study was completed examining water quality, water flow characteristics of some streams, lakes, and estuaries surrounding the Annette Islands (Pacific Rim Planners, Inc., 1979A). Data from both of these studies was combined with data collected in streams during 1980 and 1981 and evaluated in terms of how various physical and biological parameters affect salmon production in the streams and recommendations regarding management and enhancement of the streams were made. In addition, stream conditions and salmon production realized on the Annette Islands were related to conditions and production found in other Pacific Northwest locations through a literature review.

There are approximately 82 streams that drain the Annette Islands (a few other small creeks exist, but were not counted). More detailed descriptions of the major watersheds and their sub-basins is available in the Annette Island Watershed Study and Annette Islands Coastal Management Program (Pacific Rim Planners, Inc., 1979A and 1979B). The streams range in size considerably, but are of three general types:

1. those streams draining muskeg ponds, lakes or originating from muskeg run-off (e.g. Canoe Cove Creeks, Graveyard Creek), characterized by lower pH and high Tannic Acid concentration
2. those streams draining higher elevation lakes (eg. Tain Creek, Tamgas Creek) characterized by high temperatures in the summer and less variable streamflow.
3. and those streams originating from mountain run-off (e.g. Annette Point Creek, Anvil Mountain Creek) characterized by low year round temperatures and flashiness (variable flows)

Specific characteristics of each of the creek types affect salmon production as well as physical and biological factors that occur in all three creek types. The various factors that affect salmon production in streams, including factors characteristic of the stream types, fall into two general categories:

I. Physical Factors (12)

A. Hydrogeographic

1. stream bed gradient
2. bottom composition and gravel types
3. meander (sinuosity)
4. origin
5. pool:riffle ratios and pool size
6. water velocity
7. water flow (can be related to rainfall, 32,36)
8. stream depth and width
9. stream bank composition and stability
10. presence or absence of barriers to migration

B. Chemical

1. pH and cause of acidity or basicity
2. water temperature
3. clarity/turbidity
4. dissolved oxygen
5. dissolved carbon dioxide
6. total alkalinity
7. total hardness
8. dissolved and suspended solids (related to B.3)
9. conductivity
10. pollutants or toxins

C. Other

1. large organic debris presence
2. small organic matter presence
3. presence of beaver dams or other physical obstructions (including man-made ones)

II. Biological Factors

A. Extrapensatory (independent of population density - all physical factors are considered extrapensatory)

1. stream primary productivity
2. stream invertebrate abundance
3. terrestrial insect abundance (as a potential salmonid food source)
4. aquatic and terrestrial vegetation present

- B. Compensatory (freshwater survival is generally related inversely with factor, usually over a threshold number)
 - 1. escapement magnitude
 - 2. density of eggs and alevins in gravel and of fry and fingerlings in the stream
- C. Depensatory (freshwater mortality due to factor generally related inversely with population density)
 - 1. predation (although this can be compensatory also)

Many of these factors are interdependent and a complex model involving all of them has never been compiled, even though many stream models have been drawn up. Since many of these factors were examined in the Annette Islands streams, a production model could be constructed if only for each of the three stream types. However, for the purposes of estimated potential salmon production, a very simple model was drawn up utilizing survival rates realized in streams similar to those on Annette, optimal escapements based on available spawning bed magnitude and historical escapement, and relating survival and salmon migration (of both adults and smolts) to individual stream conditions. It is recommended that for future estimates of actual stream production projections, a more precise model be constructed based on weather conditions (and relating those to stream flow, changes in available rearing and spawning habitat, stream temperature, other water quality factors and miscellaneous other physical and biological factors), actual escapements, fry counts, hatchery releases, and salmon catch (commercial); in addition, changes made affecting creeks, such as logging practices, road construction, and pollution, should be taken into account prior to stream production modelling. At this point in time, there is sufficient baseline data present or currently being collected, to compose a rudimentary model similar to that suggested.

Literature Review

A thorough review of current literature is valuable in relating stream conditions and habitat characteristics found on Annette Island to similar streams and factors affecting production in the Pacific Northwest that have been well documented. Production statistics found in these other streams may provide a clearer picture of what could be expected in terms of potential production out of Annette Island streams. Factors affecting production and production statistics will be examined in each phase of salmon life history, beginning with the migration of the adults to their home streams (only factors and species that could or do occur on Annette will be covered in detail).

Adult Return Migration

Many of the migration patterns and timing of salmon are genetically determined (4); however, physical factors do affect and change run timing and success. First of all, a stream must be physically large enough to accommodate salmon. Table 1 summarizes preferred and/or acceptable habitat conditions and includes acceptable stream depths that will allow salmon passage. Temperature can also affect salmon migration, but generally, detrimental affects occur only above a certain tolerable level (see Table 1 for ranges). Burgner (4) found that earlier warmer water temperatures induced earlier sockeye migrations. Adequate dissolved oxygen levels are required for sustained swimming of salmon (high temperature during the fall can lead to decreased oxygen levels), and it has been determined that levels should not fall below 5 mg/l oxygen during migration (28). Turbidity should not exceed 400 mg/l as it abrades salmon gills and acts as a thermal barrier (28). Barriers that impede migration should be identified, whether they are falls, debris jams, or excessive water velocities, removable or stationary. Table 1 lists acceptable velocities for salmon migration. Bryant (14) states that large organic debris (LOD) does not, in most cases, block fish passage. In fact, LOD can actually aid in migration by providing "stepped falls" in places that would normally be a velocity barrier (32). Adequate streamflow are critical to migration by providing acceptable depths and oxygen levels for passage. Thompson (9) stated that stream flow required for passage was found to be generally 67% of that required for spawning. Delayed stream flows increases over the summer was shown to delay the timing of the upstream migration of pink and chum salmon (12).

Spawning

The most obvious factor affecting spawning is the amount of suitable area available. Creek size, the percentage of suitable gravels present, and stream flow generally determine the amount of area that will be available. Table 1 summarizes preferred or acceptable water depths, velocities and temperatures for the different species of salmon. Successful spawning has occurred in temperatures ranging from 2.2 to 20C; however, a sudden drop in temperature can cause all spawning to cease (28). Gravel size is important as each species has a particular range of sizes it can use. Table 1 summarizes gravel sizes acceptable

to each species. One researcher stated that, in general, optimal gravel composition for salmon is 80% 1.3-3.8cm gravels with the balance being material up to 10.2cm.(28). Cover ability (produced by overhanging vegetation, LOD submerged and above water, undercut banks, and pools) can be essential to fish waiting to spawn and nearness of cover may be a factor in spawning site selection (28). Stream flow is important during spawning as salmon not only prefer and choose water depths and velocities that are physically suited for redd building activity and that are affected by stream flow (28), but also because stream flow strongly influences the magnitude of the spawning area available. There is an optimum flow range for each creek maximizing spawning area (14). For major creeks, this stream flow - spawning area relationship can be established by measuring usable widths (remembering acceptable velocities) as a function of stream flow (34). Thompson (34) found that, in general, the optimum flow for spawning was 1.67 times that of the minimum flow, in creeks with gravel bars and uniform sections of spawning area (minimum flows were established for each creek based on presence of minimum depth and size of the gravel bars). Gallagher (8) found that 90 % of the variation in the even-year return of chum salmon and 10% of the variation in the pink salmon run was explained by variations in stream flows from September 15 - November 14 in the Puget Sound region of Washington.

Different salmon species utilize different sections of the creek, with pinks generally using lower creek stretches and chum and coho using upper reaches (12). Only pink and chum utilize intertidal spawning areas. Many salmonids prefer spawning in pool-riffle interchanges as a downwelling current is created there that penetrates gravel (good for incubation) and that may assist the fish in maintaining its position with a minimum of effort (28). Average redd areas (size of area salmon need to cover eggs laid) and area recommended for each spawning pair by species have been defined by various individuals (see Table 1).

Among the biological factors occurring during spawning that affect production is fecundity. Table 1 lists fecundity ranges found with the various species as well as fecundities observed in 1981 in returning Annette Island salmon (1981 Tamgas Creek Hatchery Egg Take Statistics). Sex ratios found were generally 50:50 and seemed to have a minor affect on production (12,37,20,28). Unsuitable stream conditions, such as low flow, can not only cause stress and increasing mortality in returning adults, but can also increase predation if fish are easier to catch. It is an obvious fact that production is directly related to the number of spawners, however, in addition, many researchers have noted the affect of spawner density on production (compensatory factor). Wickett (37) states excessive density of spawners can cause redds from early spawners to be dug up by preceding spawners. Miller (14) found that survival rates of resulting eggs was constant up to a "threshold" spawner density, above which survival began to drop off. Ricker (30) has also defined a compensatory, logarithmic, relationship between number of spawners and recruits, in which recruit production begins to fall off and even decrease with the number of spawners.

Merrell (13) also observed a spawner density - fry survival relationship along with an affect on ocean survival by the run timing in a S.E. Alaskan creek. Survival of pink and chum fry was greatest in upper reaches of the stream, which may have been partially related to increased stream gradient and spawning area quality, and where spawner densities were lowest; during years of low spawner densities, the fish tended to use lower reaches of the creek, where the gradient was lower and possibly where the spawning area was of a poorer quality (13). Gallagher (8) also observed a wider distribution of spawners over the grounds with increasing run densities (with sufficient flows, redd super-imposition actually decreased even with the large runs). In addition, offspring from odd-year run spawners showed higher survival rates than those from even-year runs that generally spawned later; the odd-year offspring may be getting a "head-start" on growth with the warmer spring temperatures (13). Taylor (33) also observed a run timing effect; early pink spawners (peaking in late July to August) were smaller and offspring resulting had lower survival rates than late spawners (peaking in September). Neave (20) mentions that not only the size and timing of the run affect survival spring, but also the "compactness" of the run, there being negative effects occurring if the salmon all return instantaneous-ly versus a staggered return. To establish optimal spawner density, without relating it to changes in spawning area and quality due to physical factors, one must keep track of fry and spawner densities over a number of years and try to maintain the spawner number that results in the highest fry densities; in many Canadian streams, the actual escapements rarely reached the optimum spawner number (37). Wickett (37) found a large variation between creeks in optimal spawner densities which ranged from .35 up to 1.4 spawner pair/yard² in three creeks.

Species interaction has been observed to affect production, Gallagher (8) finding that the magnitude of chum spawners had a negative effect on the pink runs resulting two years later. He suggests that odd-even year run phenomona may have resulted from pink-chum interactions, with an equilibrium between pink and chum runs having been reached. Pink and chum may have evolved distinct life history strategies permitting their co-existence.

Incubation

Gravel quality strongly influences egg-alevin survival, Table 1 summarizing desirable gravel sizes. The potential of spawning bed material to produce fry is directly related to permeability, with increasing percentages of fines in gravels (less than .833mm in diameter) decreasing permeability (16,37). Sediments from .1-3.3mm were found to have the most disruptive effects on stream communities. Generally, increasing percentages of fines are found with decreasing stream gradients (25), however, logging can increase the amount of fines in gravels due to siltation (16). LOD formed by logging can also trap fine sediments and then during periods of flooding, the sediment can be washed down into lower reaches and the LOD movement can scour out gravels where eggs are incubating. On the other

hand, LOD from logging can help stabilize a channel and prevent the scouring effect (logging LOD must be examined individually in each creek to determine positive and negative affects, (5,32). Fines in the gravel prevent water flow which in turn prevents dissolved oxygen (D.O.) from reaching the eggs. Thompson (34) states that a .8 mg/l intergravel D.O. is required before the eggs hatch and .5 mg/l required after hatching to the emergence of the fry from the gravel. However, Reiser and Bjornn (28) list higher critical levels for chum at 1.67 mg/l during the pre-eyed stage and 3.70 mg/l after the eyed stage. High fall temperatures (sometimes caused indirectly by logging if no buffer strip is left) can also cause a decrease in D.O. levels and low temperatures can, if stream flows are also low, cause egg freezing in the gravel (10,36,37). Gravel bed depth and the irregularity of the stream bed surface can also affect water flow through gravel (28). Adequate stream flow both carrying oxygen to the eggs and alevin and preventing eggs from freezing during periods of low temperature, is essential to early life survival. Many researchers have shown, however, the detrimental scouring effect too much stream flow or flooding can result in, causing heavy egg mortality (8,10,14,15,36,37). Wickett (37) recorded an 8-fold variation in stock resulting from an area due to gravel scouring and overriding all other factors affecting run size; also a scoured creek does not regain its former stock as quickly as a creek not affected by flooding because some permanent habitat damage has occurred. Gallagher (8) found that deviation from the lowest stream flows in the Puget Sound region had a negative affect on chum returns (causing 10% of the variation during even-year runs) and high January precipitations had a negative effect on pink returns (causing 65% of the variation in run size). Fringe areas that were covered by high flows during spawning are often left to desiccation and freezing during the winter low flows (12); since rainfall is often lower in January in southeast Alaska, loss of fringe area is probably a common occurrence on Annette Island. Thompson (34) found that optimum incubation stream flows were approximately equal to minimum spawning stream flows established, and successful incubation and fry emergence occurred at 2/3 of the required flow for spawning.

Density of eggs in the gravel can profoundly affect survival. Hunter (12) found that numbers of fry emerging gradually falls off to a maximum with increasing numbers of pink and chum eggs deposited and that similarly, percentage of eggs surviving to fry decreases with increasing numbers of eggs deposited. Wickett (37) obtained similar results stating that stream velocity and temperature is what limits the density of eggs that will maximize survival. Predation of eggs in the gravel occurs, but is not covered well in the literature; the magnitude or extent of the predation and its resultant affect on production is not known.

Juvenile Rearing and the Freshwater Environment

Defining acceptable and preferred habitat and stream size for juvenile salmon is much more complicated than for any other phase in a salmon's life history, because not only are habitat preferences different between species, but the habitat itself is hard to define. In general, the lower the channel elevation, the higher the fish biomass found (25). Pink and chum fry generally depart for the estuary soon after emerging from the gravel, and freshwater habitat requirements for them are not well defined; however, chum fry generally do spend a longer period of time in freshwater and migrate out at a larger relative size than do pinks (8,12). Canadian researchers found that pink and chum fry outmigrations generally peak between mid-April to mid-May (12). Because pink and chum migrate out at such an early stage in their life, early marine environmental factors versus freshwater factors are what affect resulting production most profoundly. Morrill (18) stated that indeed, marine survey indices of chum fry abundance were a much more accurate base for production prediction, than were pre-emergent fry indices. The early marine environment will be covered later.

Coho, sockeye, steelhead, Dolly Varden, and cutthroat remain in the freshwater habitat for at least one growing season and are therefore much more affected by freshwater production factors (physical and biological). In general, coho fry prefer pools and backwater areas and generally spend one year in freshwater, steelhead (spending two years in freshwater) and trout prefer riffles, and Dolly Varden prefer similar habitat to coho, but are much less aggressive (10,28); therefore, species composition and production is strongly affected by quantity of each habitat type. With coho production, pool abundance is extremely important and Platts (25) found that the highest abundance of fish occurred in streams with 30-50% of the area in pools (versus riffles). One study showed that in an artificial stream, when cover was quadrupled and number of pools tripled, the fish biomass tripled (10). On the other hand, it has been shown that creeks with lower pool-riffle (p:r) ratios may be more conducive to increase fish productivity in areas where the water is infertile (25), probably a more important consideration where management will be aimed at steelhead, chinook salmon, or trout.

Streamflow has a profound affect on the amount of habitat available and can change the p:r ratio. Many researchers have found strong correlations between streamflow and coho production in Washington and Oregon (10,31). Unfortunately, the flow requirements are least known for salmon in the fry-emergence to adult period even though during the rearing, flow is probably the most critical factor determining survival because of its interactive affect on many other physical and biological factors (34). However, Thompson (34) has recommended guidelines for optimal rearing flows: he suggests adequate depths over riffles, a p:r near 50:50, with 60% of the riffle area being covered by flow, riffle velocities of 1-1.5 fps and pool velocities of .3-.8 fps, and with most of the stream cover being available as a shelter for young fish. Giger (9) recommends an optimum rearing flow at which increases in wetted perimeter of the stream with streamflow begin to fall off and amount of shelter available per stream mile is maximized; he stresses

the interaction of stream flow to other factors affecting production lists acceptable stream depths and velocities for various species (see Table 1).

Amount of available cover can be a critical factor (sometimes a determining factor - 21) affecting fish biomass and changes in stream flow can change the amount of cover considerably (28). Cover is created by overhanging stream-side vegetation and root wads, undercut banks, pools, LOD and other obstructions. A lowered stream flow can "pull" water away from the banks, decreasing the amount of stream-side cover available and uncovering some of the submerged cover available (9). A decrease in the amount of stream-side cover can also indirectly decrease food availability if salmon are depending on food from terrestrial sources, as many insects available "drop" into the stream from overhanging riparian vegetation (28). Large variations in flow causing stream flashiness can also be detrimental to production (as with incubating eggs) by "washing out" or destroying cover. Logging can also affect the amount of cover available in the stream; blowdown and LOD created by logging can initially increase the amount of cover available, but if no buffer strip is left and the LOD washes out, a resulting decrease in cover and increase in stream riffle area will occur (4). A buffer strip allows a future source of LOD and stabilizes the streambank, having a net positive affect on available cover and rearing habitat (5,32). On the other hand, it was found that in small second or third order Cascade Range streams, logging that left sections of stream open, with no buffer strip increased stream primary productivity and insect productivity resulting in increased fish biomass; however, this was not the case for larger, lower gradient streams (19).

Food availability is a primary factor determining the stream production potential and may regulate fry density and distribution (28). Water quality, depth, velocity, and substrate composition all profoundly affect food abundance. Even stream size affects biological productivity, wider streams being less productive per unit area than narrower ones, depending primarily on water depth and velocity (9). Primary productivity is the base of the food chain in swift water areas and detritus forms the base in depositional areas, both affecting the numbers of aquatic invertebrates present. Riffle areas were found to be the most productive in terms of aquatic insects, which move and become "drift" (especially at night - 9), and food for salmonids. Therefore, stream velocities can affect the amounts of "drift" available with low velocities reducing drift; in general, Giger (9) states that stream velocities under 15 fps and over 3 fps (the optimum occurring at 1-2 fps, 1.4-3.5 fps according to Reiser and Bjornn, 28) have a detrimental affect on drift abundance. Water depth must be adequate for insect production, with highest productivities reported between .15-.9m (28), the optimum range being .46-.91m (28).

Substrate composition regulates benthic insect distribution, the highest productivity occurring with rubble (6.6-17.8cm in diameter) and a general decrease in the number of insects in the progression rubble-bedrock-gravel-sand (9,28); predominately coarse gravel (3.2-7.6cm) and rubble (7.6-30.4cm) areas generally produce the most number of insects. Salmon utilize mayflies (Ephemeroptera) and stoneflies (Plecoptera) more heavily than caddis-flies (Trichoptera) (28) and if low numbers of aquatic insects occur, salmon will switch to depending mainly on terrestrial sources for food. Nickelson and Hafele (21) found that a 75% flow reduction decreased aquatic insect numbers and drift; however, salmon food type simply shifted to terrestrial and adult aquatic insects.

Water quality also influences food availability, as well as directly influencing juvenile salmonid growth and survival. Low pH and a lack of Calcium (associated with low water hardness) can be a cause of low stream productivity, a neutral pH and hardwater being desirable (10,28). Low pH and low water hardness often occurs in Annette Island streams and may be limiting factors in production. Water temperatures influence fry growth rates (warmer temperatures increase metabolic rates), swimming ability, dissolved oxygen concentrations (above 15C, D.O. regulates the active metabolism rate of young sockeye) ability to capture and use food (in higher temperatures, stream salmonids require more food) and ability to withstand disease outbreaks (28). Table 1 lists preferred temperature ranges and optimal temperatures (maximizing growth under other optimal conditions) and lethal temperatures; with warmer temperatures versus those on the lower end, having the most deleterious affects on survival. Dissolved oxygen concentration is important to growth, with amount of food consumed, weight gain rate and food conversion falling off below about 3.5 mg/l D.O. with coho (age 0+) (28). High turbidities (levels of suspended solids) can abrade and clog fish gills, reduce feeding and cause fish to avoid some areas (28); therefore, during flooding, streams with a high amount of deposited silt and mud can be undesirable to juvenile salmonids. High turbidities are generally not a problem on Annette Island. Pollution and siltation from logging often negatively affects juvenile salmon growth and survival.

Density dependent factors also come into play in stream fry production potentials. Coho fry are very aggressive and territorial and will defend a rearing "space" or "focal point" to which they will repeatedly return ferociously (28). In contrast to pink and chum, whose production is largely determined by available spawning area and gravel quality, coho production is often limited by the total amount of rearing space available in a stream. High densities often result in a decrease in the average size of the fish migrating out, for all species, which could be the result of competition for limited amounts of food and having to rear in a non-preferable microhabitat (9). Increases in flow can increase rearing space available and indirectly cause visual isolation (important to coho) which in turn increases the stream's production potential (9).

Table 1 lists densities of salmon eggs and fry observed and gives an idea of what a creek can produce knowing area available. Predation can also affect fry survival, but has a more profound affect on production during smolt migration and in the estuary.

In general, good rearing habitat for anadromous salmonids consists of a mixture of pools and riffles (riffles less than 20%) adequate cover, water temperatures averaging between 10 and 15C during the summer, dissolved oxygen at near saturation levels, suspended solids less than 25 mg/l, and riffles with less than 20% fine sediment (less than 6.4mm in diameter) (28). Many of Annette Islands streams possess most of these characteristics. It has been shown that variation in freshwater conditions are the dominating factors controlling the general population level and stock size; ocean factors impose some additional variation but only affect production after the general population level has been set by freshwater factors (27). Freshwater physical factors are much more variable than ocean physical factors (20). In modelling stream production it is recommended that a habitat rating system be devised that utilizes multiple regressions and takes into account factor interaction and the percentage of variable caused by each factor (10). Gallagher (8) and Nickelson and Hafele (21) have constructed such models.

Smolt Migration and the Early Marine Life

Several physical and biological factors that affect production occur during the downstream migration of smolt. Temperature not only affects creek productivity, but it also affects the timing of smolt migration. Foerster (7) found that sockeye smolt migration commencement coincides with a vernal rise in lake temperature, in the spring the threshold occurring at about 4.4C, and that migration ceases once a summer thermocline has formed (at below 10C); those smolt that did not migrate before the water stratification occurred, stayed and migrated the next spring. Also, bright, calm days accelerated migration and rain and overcast slowed it (7). Run timing itself has an affect on survival. Taylor (33) found that early migrating pink hatchery fry (departing between February 27th and March 19th) showed lowered ocean survival than hatchery fry migrating later (April 10th-April 22nd); however, the early fry were smaller which in itself may have affected the differential survival. Wild Alaskan pink fry were found to migrate from early March, peaking in mid-April, to mid-May from the Taku River (east of Juneau, Alaska). Chum fry migration peaked in early May, coho and sockeye smolt migration peaked in May and June (6). Increased stream flows have been correlated to peaks in juvenile migration; increased flow and turbidities may assist juveniles in swimming downstream and avoiding predators (6). Juvenile mortality increases with the distance the young fish must travel to get to saltwater and decreases with increasing numbers of migrants exiting (20), a depensatory process possibly related to predation. Size at migration has been shown to affect survival, in general, larger fry and smolt experience increased ocean survival (6,26); in addition, larger

coho smolt seem to migrate out earlier than smaller ones (6), which may also affect production. Sockeye smolts migrating (yearlings) varied from 8-20cm in length (6), and averaged 10cm long in another study (11); chinook and coho smolts varied from 15-27 cm when migrating. Increasing the rearing time for chum resulted in the release of larger fry, can also increase ocean survival (6). Size at time of migration may be related to predation, which has been recorded as being an important factor in decreasing fry output (12). Neave (20) recorded a predation efficiency that ranged from 5-8.6% of the migrating pink fry in British Columbia streams; predator efficiency decreased with increasing numbers of migrating fry (exhibiting the depensatory effect). Sculpins were found to be efficient predators of pink and chum fry, consuming 15 fry a day; coho smolts were even more efficient, consuming 20 fry per day (12). Sculpins are commonly found at Annette Island creek mouths and predation mortality should be considered in any production model.

Ocean survival is largely determined by survival rates in the estuary and early marine life of salmon (26). The summer sea water temperature was found to be inversely correlated with total subsequent pink salmon abundance, lower temperatures enhancing numbers (36). Gallagher (36) found that pinks were enhanced by cooler sea surface temperature whereas warmer sea water temperatures enhanced chum and salinity was found to be directly related to chum brood returns, increasing salinities in Puget Sound having a positive affect on chum fry survival (this salinity affect occurs with both pink and chum fry - 36,37). Late summer rainfalls enhance pink and chum stocks (37). Increased winter precipitation also had a positive affect on chum brood in Puget Sound (8). Upwelling can profoundly influence growth and survival of juvenile salmonids by affecting plankton blooms, the food source (6). Upwelling effects decrease as you go offshore and this is consistent with the fact that the most abundant and diverse micro and macro plankton items occur in-shore (6). Pink and chum fry prey in shallow near-shore waters in Puget Sound, consisted of epibenthic (just off the bottom) prey items with a change to zooplanktivorous items occurring at the May (8). Pink seemed to prefer invertebrate eggs as food, whereas chum preferred smaller gammarid amphipods and harpacticoids, although they do eat alot of the same things. Coho exhibit a flexibility in choice of food items, both in freshwater and in saltwater; this explains why it has been difficult to tie changes in coho abundance with herring population changes (6). In Alaska, food was not found to be a limiting factor in production of pink and Bristol Bay sockeye (26). Peterman (26) demonstrated that predation during the early marine life was a significant factor affecting survival of Alaskan pinks and sockeye; parasitism and disease also took their toll and all these three factors together seem to have a more significant affect on survival than did competition and density-dependent factors. In general, it was found that when pink, chum, sockeye, chinook, and coho fry and smolt go out to sea, they stay in coastal and inside waters, whereas

steelhead seem to go directly out to sea (11). Pink, chum and sockeye were found together in the estuary and near the coast and although coho and chinook were alot fewer in abundance and were more wide ranging than the others, all five species remained near the coast for their first summer; no evidence of food competition among smolts was recorded (11). In contrast Gallagher (8) found that large numbers of pink fry had a negative affect on growth of chinook and sockeye smolt and a pro-profound affect on chum brood returns, partly causing the odd-even affect on pink and chum runs in Puget Sound. Age class ratios also varied in odd and even years. Chum return as 4 or 3 year olds and usually 3 year olds make up only 1/3 of the run (8). Gallagher found that in odd years (corresponding to strong pink runs), the 3:4 year old ratio is 50:50 (which would shift alot of chum over to becoming even year spawners) versus in even years when it is 35:65. Similarly in B.C. where strong pink runs occur in even years, the same effect occurs with a shift to a high percentage of 4 and 5 year old chum during odd years (weak pink runs) suggesting again, the presence of an equilibrium between pink and chum runs allowing their co-existence (8). Peterman (26) did not find a competitive effect between pink and sockeye fry in Alaska and did compare survival rates realized. Table 2 summarizes various survival rates realized in life history phases of Pacific salmon, many of which include effects on survival during the early marine life.

Marine Survival and the Ocean Environment

Less is known about factors affecting survival in this phase of the salmon's life history than in any other phase. As was stated earlier, freshwater factors and factors affecting the early marine life of salmon generally determine production resulting, however, ocean factors are important nevertheless.

Fishing mortality is probably the single most important ocean factor affecting production. It has been observed that return rates of salmon realized in Alaska and British Columbia are generally higher than those realized in Washington and Oregon; this may have to do with the fact that Washington and Oregon smolts more north and may migrate a farther distance in coastal areas during their ocean lives than do Alaskan smolts (11). This increased distance may subject them to more inshore and offshore fisheries and inshore predators, having to traverse Canadian and Alaskan waters. Therefore, ocean survivals realized in Washington, Oregon and Southern B.C. may not be representative of rates realized in Southeast Alaska. It has been noted that pink and sockeye smolts, as well as adults sometimes migrate together (22), however, competition has not been demonstrated. Compensatory responses to fishing pressure does occur, but it mainly occurs in the freshwater environment. Pinks have generally higher fishing mortalities than do chum, chum fishing mortality was recorded to vary from 47-82% (20). Neave (20) stresses the fact that increased fishing pressure can only be compensated for with increased freshwater survival,

TABLE 2. REALIZED SURVIVAL RATES IN BRITISH COLUMBIA AND ALASKA

FRESHWATER SURVIVAL

Egg-Emergent Fry*:	Pink	10% - Average for 5 Alaska and B.C. creeks (17) 5-20% - B.C. (26) .88-16.47%, B.C. creek averages (12)
	Chum	.99-19.41% - B.C. creek averages (12)
	Pink and Chum Combined:	1-22.8%, average 9.6% - S.E. Alaska (13) 1.16%, S.E. Alaska average (20) 5-13.2% B.C. average (20) Egg Lost - 8-98% mortality, of remainder, 5.7-31.1% survival in B.C. (12)
Egg-Fingerling (Migrating) -		
	Pink and Chum	.08-15.09% B.C. (20) 5-20%, actual measured - 11% - B.C. (3)
Fry-Smolt:	Sockeye	21-70% in B.C. (26)

* Generally, chum, coho, sockeye and steelhead utilize better overall quality gravel than pinks and may experience higher average survival rates (especially within a creek).

MARINE SURVIVAL

Fry-Returning Adult:

Pinks	2-9% - B.C. (26) .7-5.2% - B.C. (12) 2-22%, average 3.4% - For 5 Alaska and B.C. creeks (17) 11% (95% exploitation rate) - B.C. (27)
Chum	.85-2.6% - B.C. (12)
Pink and Chum Combined	.29-6.75% - B.C. (12) .5-3.5%, average 2% - Alaska Fish and Game Statistic (1)
Sockeye:	.5-4.1% - B.C. (26) .5-2.5%, average 1.5% - Alaska Fish and Game Statistic (1)

Smolt-Returning Adult

Coho	6-16%, average 10% - Alaska Fish and Game Statistic (1)
Sockeye (Age 1+)	2-87% - Bristol Bay, Alaska (26)
Sockeye (Age 2+)	4-70% - Bristol Bay, Alaska (26)
Sockeye	2-10% - B.C. (26)

Pink Salmon

Marine Survival Estimation

Model (17):

$$S_m = \frac{R}{E \times S_f}$$

R = Return per spawner, average 3.06 for Alaska
E = Fecundity ÷ 2
S_f = Freshwater survival
S_m = Marine survival

and using an assumed ocean mortality of 5%, he predicted required freshwater survivals to maintain stocks given different fishing mortalities: at little to no fishing pressure, freshwater survival could fall below 10%, however, with fishing mortalities at 80 and 90%, freshwater survival had to be 12 and 23% respectively. McNeil (17) has devised a simple model to estimate pink salmon marine survival rates:

$$S_m = \frac{R}{E \times S_f} \text{ where}$$

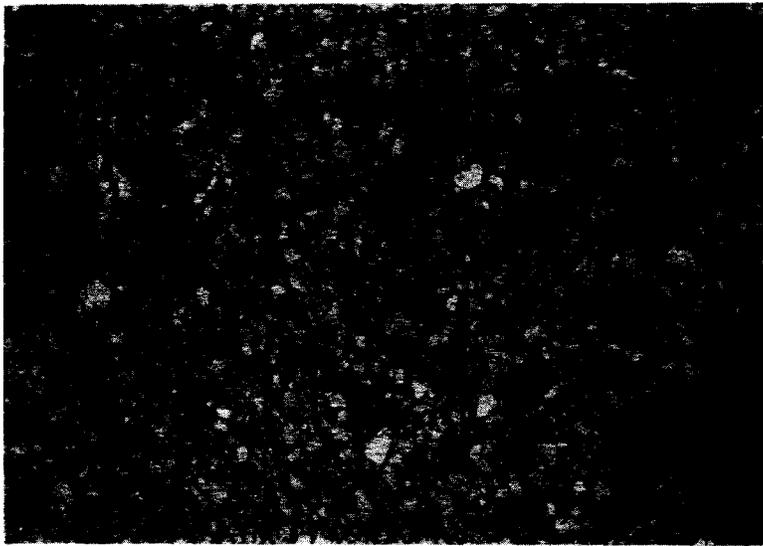

R = Return per spawner (averaging 3.06 in Alaska)

E = Fecundity ÷ 2 (since it takes two spawners)

S_f = Freshwater survival (%)

S_m = Marine survival (%)

This model could be applied to Annette Island pink salmon stocks as well. McNeil (17) stresses that natural populations of salmonids are more severely affected by increased fishing pressure since freshwater survival cannot be manipulated as it can with hatchery reared fish. Wright (38) recommends maintaining natural runs of coho stocks on a sustained yield basis with average catch:escapement ratios of 3:1 (overall fishing rate of 75%); hatchery stocks can withstand 19:1 ratios (overall fishing rates of 95%) due to the increased egg to smolt survival. Ricker (29) made an observation that has to do with ocean growth versus survival (that has been stressed so far). He observed that the average instantaneous rate of growth per month in the final year is .28 for pinks and .12 for chum and that early-opening fisheries do not allow fish caught to grow to potential; therefore, the yield-in weight is lower for early fisheries than for later ones. The overall average ocean mortality for salmon over 30cm long was found to be .2 per month (29). Many of the other causes of changes in production due to ocean factors are unknown; however, at this point, a model using average ocean survivals found on Annette Island or adjacent areas should be sufficient for predicting production given an estimate of the outmigrating fry or smolts present.

**Summary of Production
Potentials & Conclusions**

Utilizing some of the survival rates and production statistics listed in Tables 1 and 2, a simple production model was constructed. Table 3 outlines the statistics and model used to calculate potential production statistics. Fecundities listed are those estimated from salmon returning to Annette Island in 1981 (to the Tamgas Creek Hatchery) and survival rates are those that are used by the state of Alaska in their estimates and include survival realized here in Southeast Alaska. The marine survival rates used are quite conservative and in reality, ocean survival rates often surpass those listed. As a result production potential estimates are conservative and production can in reality far exceed (doubling and tripling in some cases) the potential as well as fall below when underescapement occurs. Tables 4 and 5 summarize the recommended escapements and potential productions estimated for all the creeks currently producing salmon or with potential production abilities without any enhancement. It should be emphasized that often, when historical escapement counts were listed and when much of the available spawning area available was of marginal quality, recommended escapements listed were not strictly calculated by the equation given in Table 3, but were adjusted considering the additional information available. Also, spawning areas were split up into areas utilized only by pinks and chum (e.g. intertidal areas) and those utilized only by coho and sockeye (e.g. upper lake tributaries), as well as areas pinks, chum and coho utilize. In general, coho as well as chum tend to spawn farther up the creek, in larger and generally better quality gravels than do pinks; sockeye utilize only those tributaries that empty into an alpine lake. Therefore, production potentials were often not uniformly calculated (except that similar rates were used in the estimates) and individual stream characteristics, geometry and historical escapement data were employed to hopefully increase the accuracy of the estimates.

Water quality factors were not generally considered in the estimates calculated, except those that excluded salmon production entirely. Comments were made in the individual stream survey forms and in general, low pH (usually resulting from high tannic acid concentrations) and low water hardness were water quality factors found that could have a limiting affect on production, affecting only coho and sockeye fry that have freshwater rearing periods. Pollution was not found, except in Sawmill Creek, to be a limiting factor.

The other physical factors that probably affect production most profoundly in Annette Island streams are poor gravel quality and streamflow flashiness. Moderate to heavy gravel compaction due to fines mixed in the gravel is quite common, especially in low gradient streams draining muskeg, and can cause heavy mortality of incubating salmon eggs. In streams with a highly variable streamflow, especially those draining steep slopes, gravel scouring and changes in the gravel areas submerged probably reduces survival

TABLE 3. PRODUCTION STATISTICS AND MODEL

Recommended Redd Areas per Spawning Pair (28)	Fecundities (Average Number of Eggs Per Female)
Pink .6m ²	1500
Chum 9.2m ²	2500
Coho 11.7m ²	2850
Sockeye 6.7m ²	2400

I. Spawning area available (estimate) ÷ recommended area per spawning pair = recommended escapement of spawning pairs.

II. A. Recommended spawning pairs (= number of females) X fecundity X egg loss rate (1%) = potential number of eggs buried in in the gravel.

B. Potential number of eggs buried X survival rate (egg to emergent fry) = potential number of emerging fry.

Survival rates used in calculations:

Gravel Quality	Marginal - Poor	Fair - Good	Excellent
For all Species:	1.2% (1)	10%	20%

C. Potential number of emerging fry X marine survival rate (includes fry to smolt survival rate for coho and sockeye) = potential production

Marine survival rates utilized

2% for pink, chum and coho (1)

1.5% for sockeye (1)

of eggs and alevins incubating in the gravel. Wherever applicable, if either of these factors occurred, the lowest freshwater survival rate (1.2%) was utilized in calculating the estimate.

In a few cases, namely the creeks along the eastern border of and emptying into Tamgas Harbor, man-made obstructions may limit production. The B.I.A. road was constructed with culverts, but often these culverts looked to be impassable and the slash and debris in the creek resulting from the construction strongly affected and changed the stream channel. Two creeks surveyed and one unsurveyed were affected by this construction (see the individual stream survey forms).

Most of the streams surveyed did possess physical characteristics falling into the preferred or acceptable ranges listed in Table 1. Temperature, LOD present, water depths and velocities were found to be generally acceptable for salmon production except for the problem factors listed above; characteristics that affect production are stressed within the individual stream survey forms.

As outlined in the introduction, Annette Islands' creeks generally fall into one of three types: muskeg drainage, alpine lake drainage, and mountain slope drainage. Tables 4 and 5 split the streams into these types and watershed numbers are listed for identification of individual streams. Only 53 creeks of the 77 surveyed currently have salmon producing potential, of these, 51% were found to drain muskeg (type 1), 11% drain alpine lakes (type 2) and 38% drain mountain slopes (type 3). However, type 1 creeks only potentially produce 19% of the salmon returning to Annette Island. Type 2 creeks produce 54.5% of the salmon and type 3 creeks, some of which drain into alpine lake systems (conducive to salmon rearing and smolt survival), produce 26.5% of the salmon potential production. These mountain drainage streams also produce 60% and 59% of the potential production of coho and sockeye respectively. Alpine drainage lakes, such as Nadzaheen, South Crab Bay Creek and Kwain Creek, potentially produce the bulk of the pink and chum salmon (57% and 40% respectively). Creeks were also split in major or minor streams based on their quality of spawning and rearing area and potential production; 38% of the creeks are considered major creeks and yet these potentially produce 95% of Annette Islands' salmon resource. In contrast the minor creeks (62% of the total) potentially produce only 5% of the salmon (see Table 6).

Tables 4 and 5 do not include creeks surveyed that possess salmon producing potential, but that currently do not, due to barriers preventing migration. Many of these streams have suitable spawning and often excellent rearing areas, but unless enhanced by the construction of a fish passage device, they will not produce anything but trout and Dolly Varden. Kwain Creek, the Triangle Lake System (including tributaries) and the Todd Lake System (including tributaries) currently possess the greatest potential salmon production with enhancement. See individual stream survey forms for estimates of potential production, that could occur if fish passages were constructed, based on the model give in Table 3.

TABLE 6. POTENTIAL PRODUCTION OF SALMON ACCORDING TO STREAM SIZE AND TYPE IN PERCENTAGE OF THE TOTAL

	Major	Minor	Type 1	Type 2	Type 3
Of Total Creeks With Potential Production	38%	62%	51%	11%	38%
Pink	94.5	5.5	19	57	24
Chum	95	5	27	40	33
Coho	93	7	10	30	60
Sockeye	97	3	0	42	58
All Species	95%	5%	19%	54.5%	26.5%

Finally, it should be emphasized that the estimates calculated in this study are rough and may not be what is experienced in reality in terms of salmon production. However, they do give resource planners a general idea of potential production on Annette Island. Marine survival rates used refer to survival expected from the time that fry emerge to the time that adult salmon return to the Annette Island vicinity. This means that many salmon produced on Annette Island are caught in other fisheries and most likely do contribute to the general salmon catch in the state of Alaska. Therefore, those potential production figures do not include catch realized by fishermen not fishing in the vicinity of Annette Island (non-Community members or Community members fishing in adjacent state waters). The total benefits the Annette Island fishermen, Annette Island Packing Company, and other fishermen fishing state waters derive from salmon production originating on Annette Island are not represented by the potential production estimates calculated.

A more precise production model can be constructed utilizing much of the data included in this study. However, it is recommended that escapement counts, water quality testing, and streamflow measurements be conducted in as many streams as possible on a yearly, scheduled basis to increase the data base available for wise salmon resource management. Many of the streams on Annette Island have adequate salmon escapements, however, a few face under-escapement and salmon production could be enhanced with proper harvest regulations that are enforced (see individual stream survey forms for identification of those streams).

Individual Stream Surveys

INTERPRETATION OF STREAM SURVEY FORMS

To assist in interpreting the Annette Islands Stream Survey Summary, the following information is provided:

There are two numbering systems used on these forms. Under the space entitled number are the statistical numbers. These are devised from the state fishing district numbers (the same system utilized by A.D.F.G.), the first three digits being the major district, the second two being the subdistrict number and the last three being the individual stream number; streams are designated by determining which subdistrict the creek empties into. The second number, under the space entitled geocode is the watershed number referring to the three digit code for each individual watershed and a two digit code for individual streams (see page 18 of the Annette Coastal Management Program).

The space entitled stage refers to the particular level of flow occurring on the date surveyed and flood height refers to how high above the stage flow the creek flows when flooding (generally this is at maximum flow).

See the Appendix I for an explanation of some of the units of measure and terminology used on these forms.

The data included on each form is given only for the section of the creek surveyed (see section surveyed); therefore, it may not be representative of the entire creek if a large portion was left unsurveyed. Also, unless stated otherwise, data given was taken only on the date listed in the "date surveyed" space. If the data included was taken on a different day, that date will be listed next to the data of concern.

Ranges of stream data given (e.g. streamflow and velocity) are only ones that have been measured or observed; the parameters could in reality go under or over the ranges given, they simply were not measured.

Water quality measurement abbreviations include D.O. which means dissolved oxygen concentration and CO₂ means dissolved carbon dioxide concentration. In general, unless streamflow is sluggish or the creek has alot of "dead" areas in it, D.O. will most likely be at saturation level due to the aeration effect of water flowing over rocks and dropping over distances through airspace.

Finally, it should be stressed again that measured distances and areas and estimated spawning areas, escapement recommendations and production potentials are estimates and should not be taken as exact parameters. Actual production realized can and does vary over 100% of the estimates given and the figures are only meant to give an idea of what the creek can produce potentially under certain conditions.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Anvil Mountain Creek		101-28-001	112-01
<u>Stream</u>		<u>Number</u>	<u>Geocode</u>
Flows N.W., .5 mi long, into Nichols Pass		Mountain run-off and springs	Steep, Timbered Mountain Slopes

<u>Sample Site</u>	<u>Temp.-Air</u>	<u>Temp.-Water</u>	<u>Ph</u>	<u>Clarity/Turbidity</u>	<u>Color</u>	<u>D.O.</u>	<u>CO2</u>	
--	--	--	--	Good water quality.				
<u>Total Alkalinity</u>	<u>Total Hardness</u>	<u>Dissolved Solids</u>	<u>Other/Overall</u>					

Spawning Area

35% gravels, 10% bedrock, 20% cobble, 15% boulders, 10% sand, 10% mud and silt.

Overall Stream Bottom Composition

Some - generally high quality gravels.
Gravel Compaction

245m² in lower section - good for Pink and Chums.

Spawning Area Available Above High Tide Mark (HTM)

None

Intertidal Spawning Area

Rearing Area

-- Few pools

Pool/Riffle Frequency (P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Mainly from overhanging vegetation; some undercut banks

Available Cover

Scarce Mainly terrestrial insects.

Aquatic Invertebrates/Available Food Source

Algae and moss in areas.

Aquatic Vegetation

Alder and scrubs in forested area - mainly hemlock and spruce.

Terrestrial Vegetation

80% canopy from alders; steep, bedrock banks provide some additionally.

Shading

Very little rearing area.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Used by Pink and Chum mainly if utilized at all.

Use by Fish

No fishing.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Check creek during migratory periods, when flow is high to see if salmon can get over beach log barrier.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/17/81	None Seen				

Survey(s) and Dates Conducted

E. Biggs, J. Yuska, 6/17/81

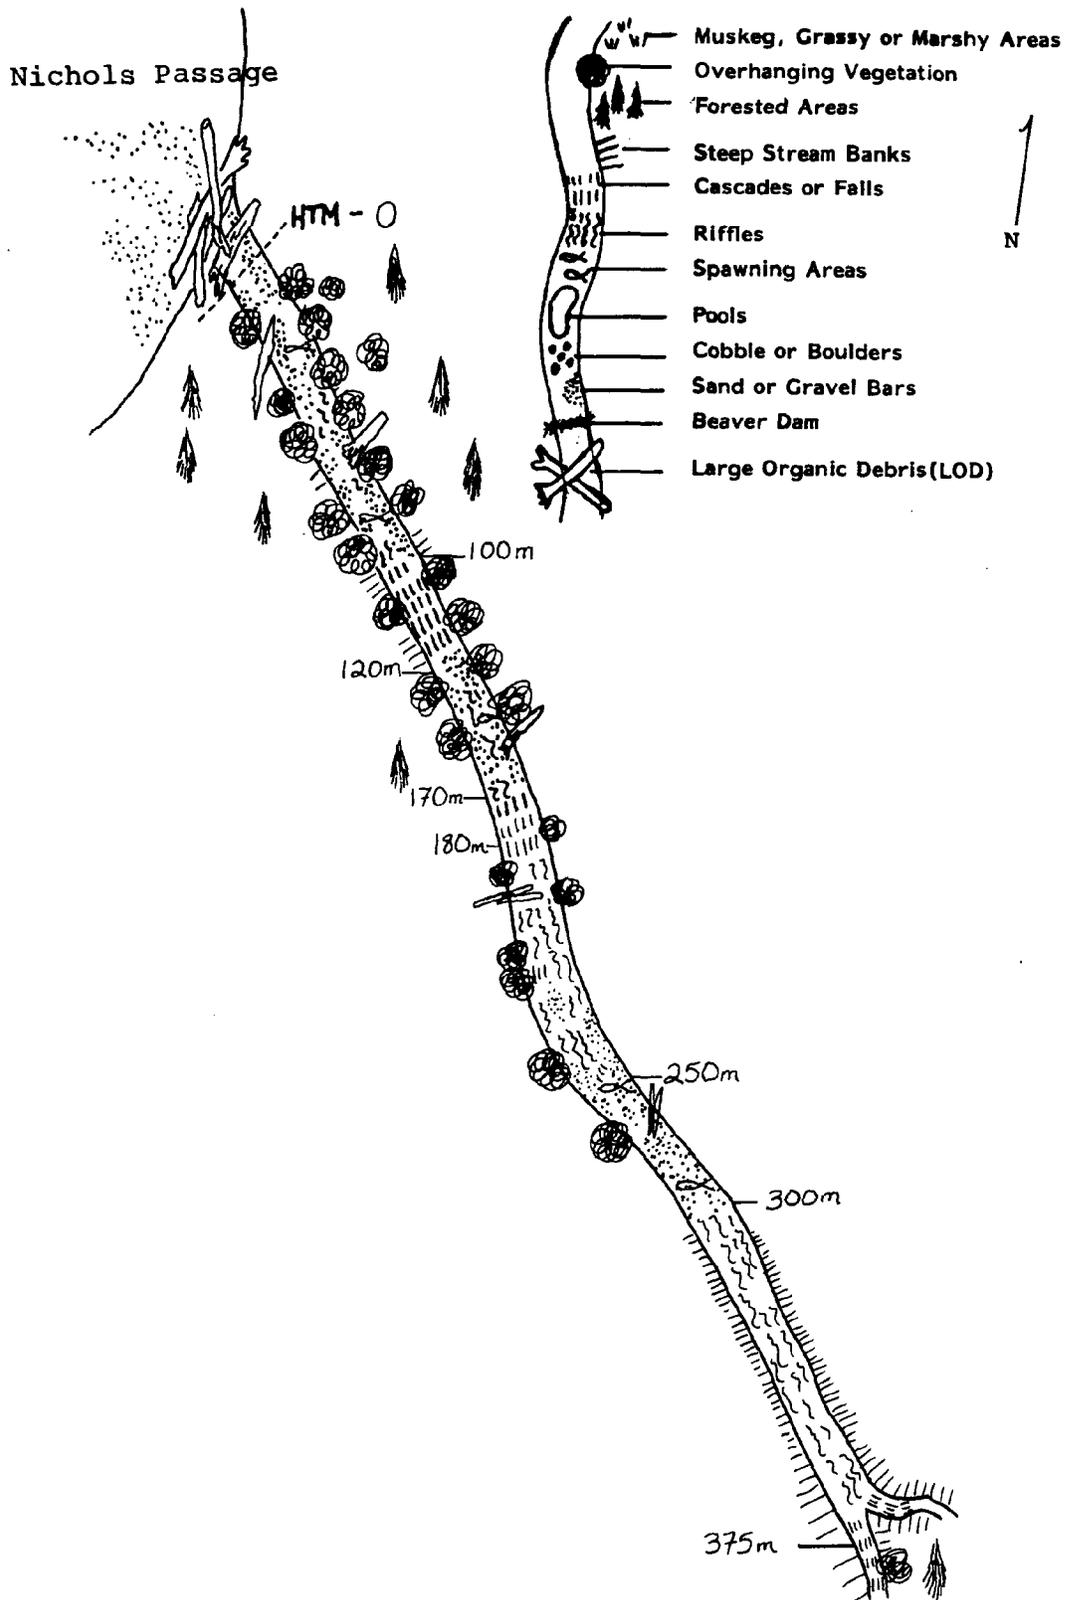

Recommended Escapement

Due to limited rearing area, coho probably do not use this creek, therefore, recommendations are made for pink and chum only. Pink probably use lower reaches and there is sufficient ground for 325 spawning pairs. Chum probably utilize the upper reaches and only 5 spawning pairs are recommended for escapement.

Potential Production Summary

Anvil Mountain Creek potentially produces approximately 165 pinks, and 25 chum that will return to Annette Island vicinity, using an emergent fry survival rate of 10% egg-fry due to the fair to good quality gravels present.

Figure 2. ANVIL MOUNTAIN CREEK

Not In Scale

ANVIL MOUNTAIN CREEK

Watershed No. 112-01
Stat. No. 101-28-001

0m High Tide Mark (HTM); below HTM a pile of beach logs create a possible barrier at low flow, low tide.

0-100m Stream looks like a spawning channel; average stream width (ASW) = 2.0m, with 80% gravels (mixed with some fine sediment) and 80% shading (alders mainly); no rearing area.

100-120m Bedrock Cascade; it may be a velocity barrier at high flow.

120-170m ASW = 1.0, 70% gravels (spawnable).

170-180m Bedrock riffle; moderate gradient.

180-250m ASW - 1m, 10% spawning gravels.

250-300m ASW = 1m, 70% spawning gravels.

300-375m ASW - 1m, 10% spawning gravels.

Above 375m Stream splits, gradient increases, and tributaries are too small for use by salmon.

Spawning Area (all in fresh water):

0-100m (below Cascades)	160m ²
120-170	35
180-250	7
250-300	35

Mainly bedrock and large boulder	Stable below falls, stable to unstable above.	5.8 Clear	One, stream forks above survey distance.				
Streambank Composition	Stability	Tributaries					
Water Quality 8/8/72: 12C	10C	5.8	Clear				
Base of falls	11.7C	9 G	5.5	Clear			
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO2
25.0 ppm	100 ppm	Total= 8.56 ppm	T.A., T.H., D.S., taken 8/8/72				
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

Below falls: 40% gravel, 11% rubble, 12% cobble, 12% pebbles, 15% sand, 10% silt. Above falls: 45% bedrock and boulders, 15% rubble, 15% cobble, 15% gravel, 5% pebble, 5% sand. Compacted a little below falls, more above falls.
Gravel Compaction

Spawning Area Available Above High Tide Mark (HTM)

Below barrier, limited - 35m² of marginal quality gravels; 25m² available above falls, limited - 10m² of mainly boulders and cobble mixed with gravels.

Intertidal Spawning Area

Rearing Area

Above falls, p:r = 1:2
Pools formed by Falls, rocks, bends and LOD, .30m above falls/to lm Largest is - 30 x 40 feet

Pool/Riffle Frequency (P:R Ratio)
Below falls: Some LOD and one plunge pool; Above Falls: from topography (banks) overhanging vegetation and LOD.

Available Cover
A few (non abundant) salt tolerant glossosmona (trichoptera), ephemeroptera, and diptera.

Aquatic Invertebrates/Available Food Source
No rooted plants; periphyton on rocks, some filamentous algae, cedar like moss on rocks.

Aquatic Vegetation
Influence of vegetation and woody debris on channel stability limited. Skunk cabbage, currant, chocolate lilies, some sedges and grasses, salmonberry and alder - timber is mainly cedar, hemlock and spruce.

Terrestrial Vegetation
Below falls: 35% due to some topography, forest and a little riparian vegetation; above falls: 50-85%.

Shading
None below falls except the pool for pink and chum fry. Some potential rearing area for coho above falls.

Extent and Quality of Rearing Area
only.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, and trout only, could use this creek.

Use by Fish

None except some deer hunters (they use cabin). Little, if any, subsistence fishing

Use by Fishermen

Wildlife Present

Comments and Recommendations

There is some potential rearing and spawning area above the falls, but the magnitude of production increase may not justify the cost of a ladder. No other improvements recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
8/8/72	None seen	--	--	--	--
6/17/81	Chum	Fry	1	--	Probably a straggler.
	Trout	Fry	15	--	Seen above falls - not abundant.

Survey(s) and Dates Conducted

E. Biggs and C. Huntingon, 6/17/81. USFWS surveyed creek on 8/8/72.

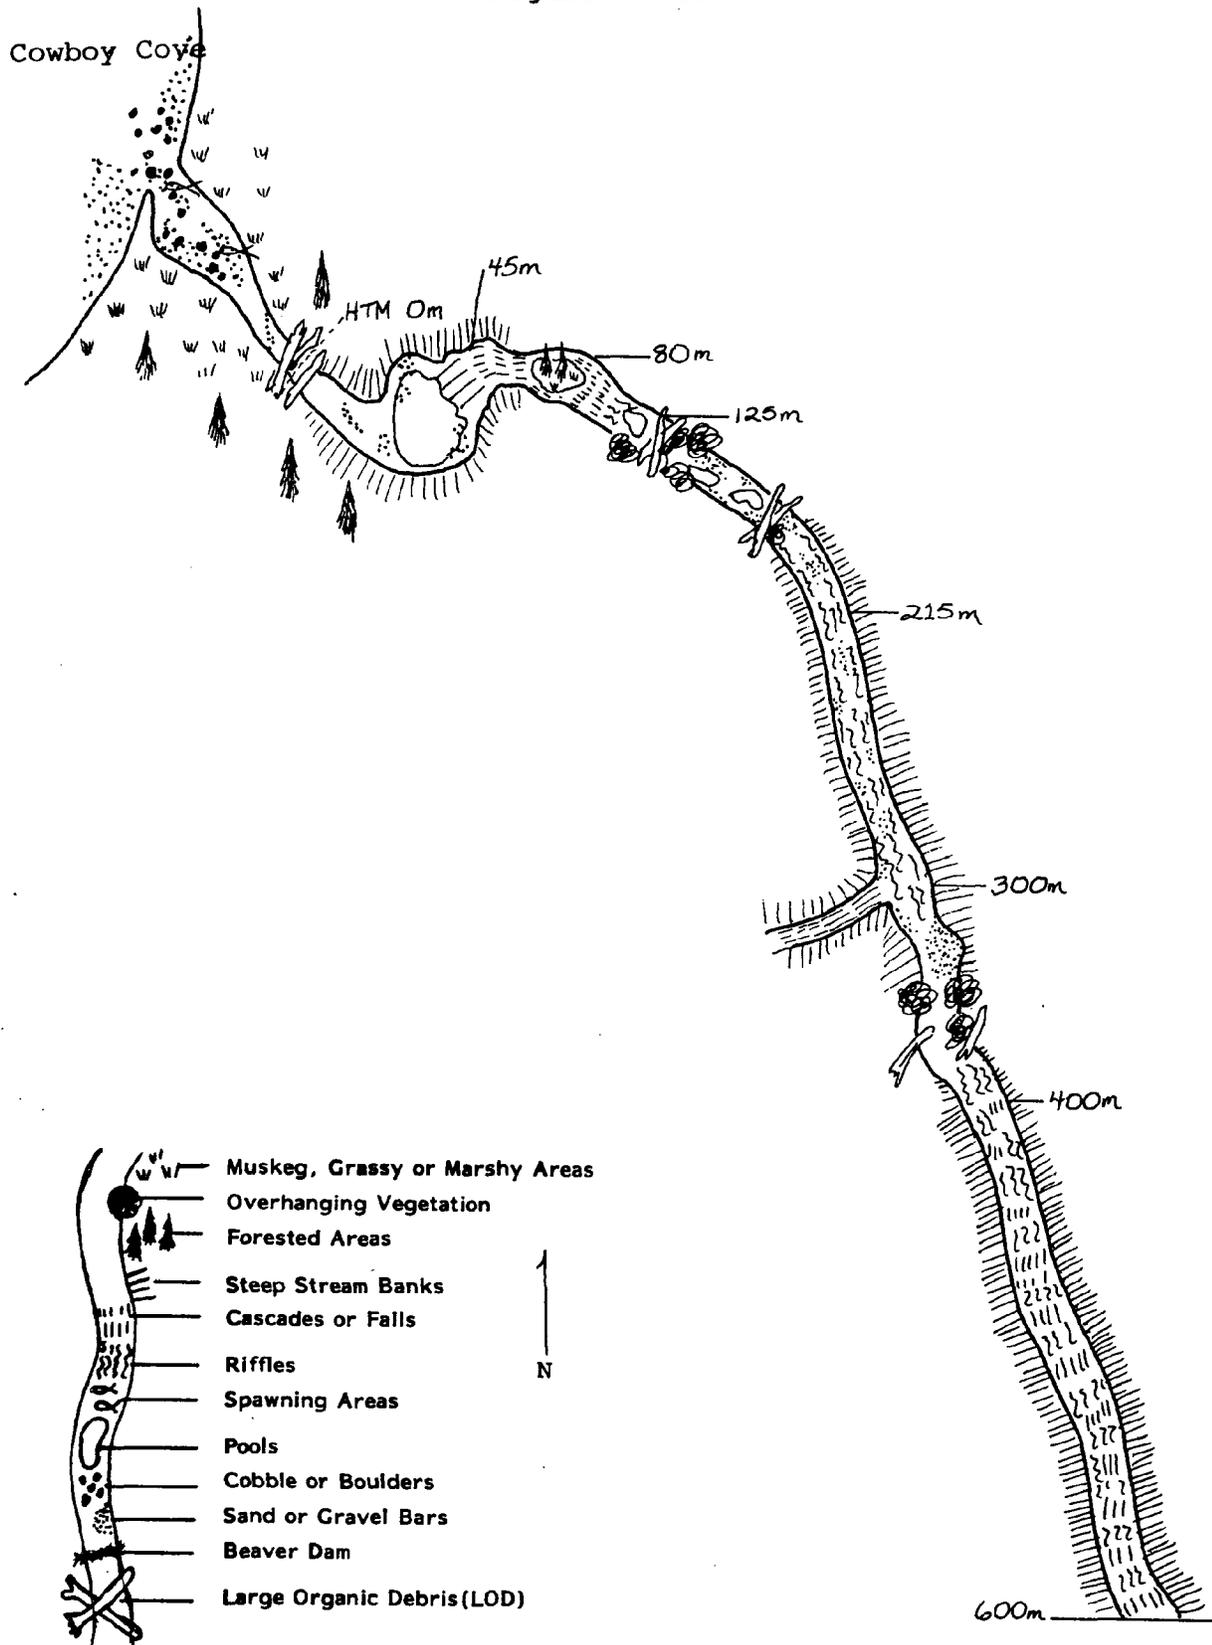

Recommended Escapement

Very limited spawning area exists in this creek. Only 60 pink spawning pairs and 3 chum spawning pairs are recommended for escapement.

Potential Production Summary

Due to poor gravel quality, only a 1.2% egg-fry survival rate is assumed: only 21 pinks, and 2 chums are expected to return given the recommended escapement numbers.

Figure 3. COWBOY CREEK

Not In Scale

COWBOY CREEK

Watershed No. 112-02
Stat. No. 101-28-002

Intertidal	Mostly cobble and boulder; only about 10m ² total is available for spawning.
0m	High Tide Mark (HTM); log pile.
45m	3.5m barrier falls over bedrock; large, deep pool created by it.
45-80m	Bedrock
80-125m	Gradient decreases, bedrock to 125m with a large pool formed by LOD and good coho rearing habitat starting at 125m.
125-215m	Good rearing habitat with a few riffles.
300m	Tributary with .3 cfs flow over a 10m high barrier cascade.
325m	Alluvial Deposit, may be part of a caved-in bank.
400-600m (End of Survey)	Boulders and bedrock bottom with steep bedrock banks; increased gradient creating a possible velocity barrier (moss appears on rocks).

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Nichols Passage Creek II		101-28-003		111-01	
Stream		Number		Geocode	
Flows N.W., over 3 mi. long into Nichols Pass.		Timbered mountain slope and muskeg flat run-off.		Timbered muskeg flats and mountain slopes. (280 acres in area.)

Total Alkalinity		Total Hardness		Dissolved Solids	
				Resistivity = 6734 ohm/cm ³ (8/8/72)	
				Other/Overall	

Spawning Area

Some foliated bedrock - shales and some clay deposit; bottom is about 60% bedrock, 10% sand and fines,

Overall Stream Bottom Composition

and about 30% gravels.

Moderate - most gravels are flat and angular - of marginal quality.

Gravel Compaction

Gravel bars present - some areas up to 50% spawning area - 1260m² area available, mostly below 1300m and

Spawning Area Available Above High Tide Mark (HTM)

due to gravel bars.

Limited - approximately 40m² of marginal quality gravels mixed with cobble and boulders.

Intertidal Spawning Area

Rearing Area

Few pools, mostly riffle and runs

Pool/Riffle Frequency (P:R Ratio)

From LOD controlled pools, undercut banks, riparian vegetation and root wads.

Ave. Pool Depth/Range

Ave. Pool Size/Range

Available Cover

Scarce - a few are present.

Aquatic Invertebrates/Available Food Source

Some algae, pennate moss - common on rocks.

Aquatic Vegetation

Devils club, salmonberry, currant and huckleberry - forest is hemlock, spruce and cedar.

Terrestrial Vegetation

80-90% shading, 70% due to vegetation and 10% due to canopy (trees).

Shading

Not extensive - some good areas exist around LOD, channel braids (side channels), and undercut banks

Extent and Quality of Rearing Area

and pools.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, coho and cutthroat use creek.

Use by Fish

Limited use by fishermen - may be some commercial fishing outside cove.

Use by Fishermen

Wildlife Present

Deer tracks abundant.

Comments and Recommendations

Little could be done to enhance stream.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
8/8/72	None seen	--	--	--	--
6/17/81	Cutthroat	Adult 4.5 inches	1		

Survey(s) and Dates Conducted

E. Biggs and J. Yuska, 6/17/81 and by USFWS, 8/8/72.

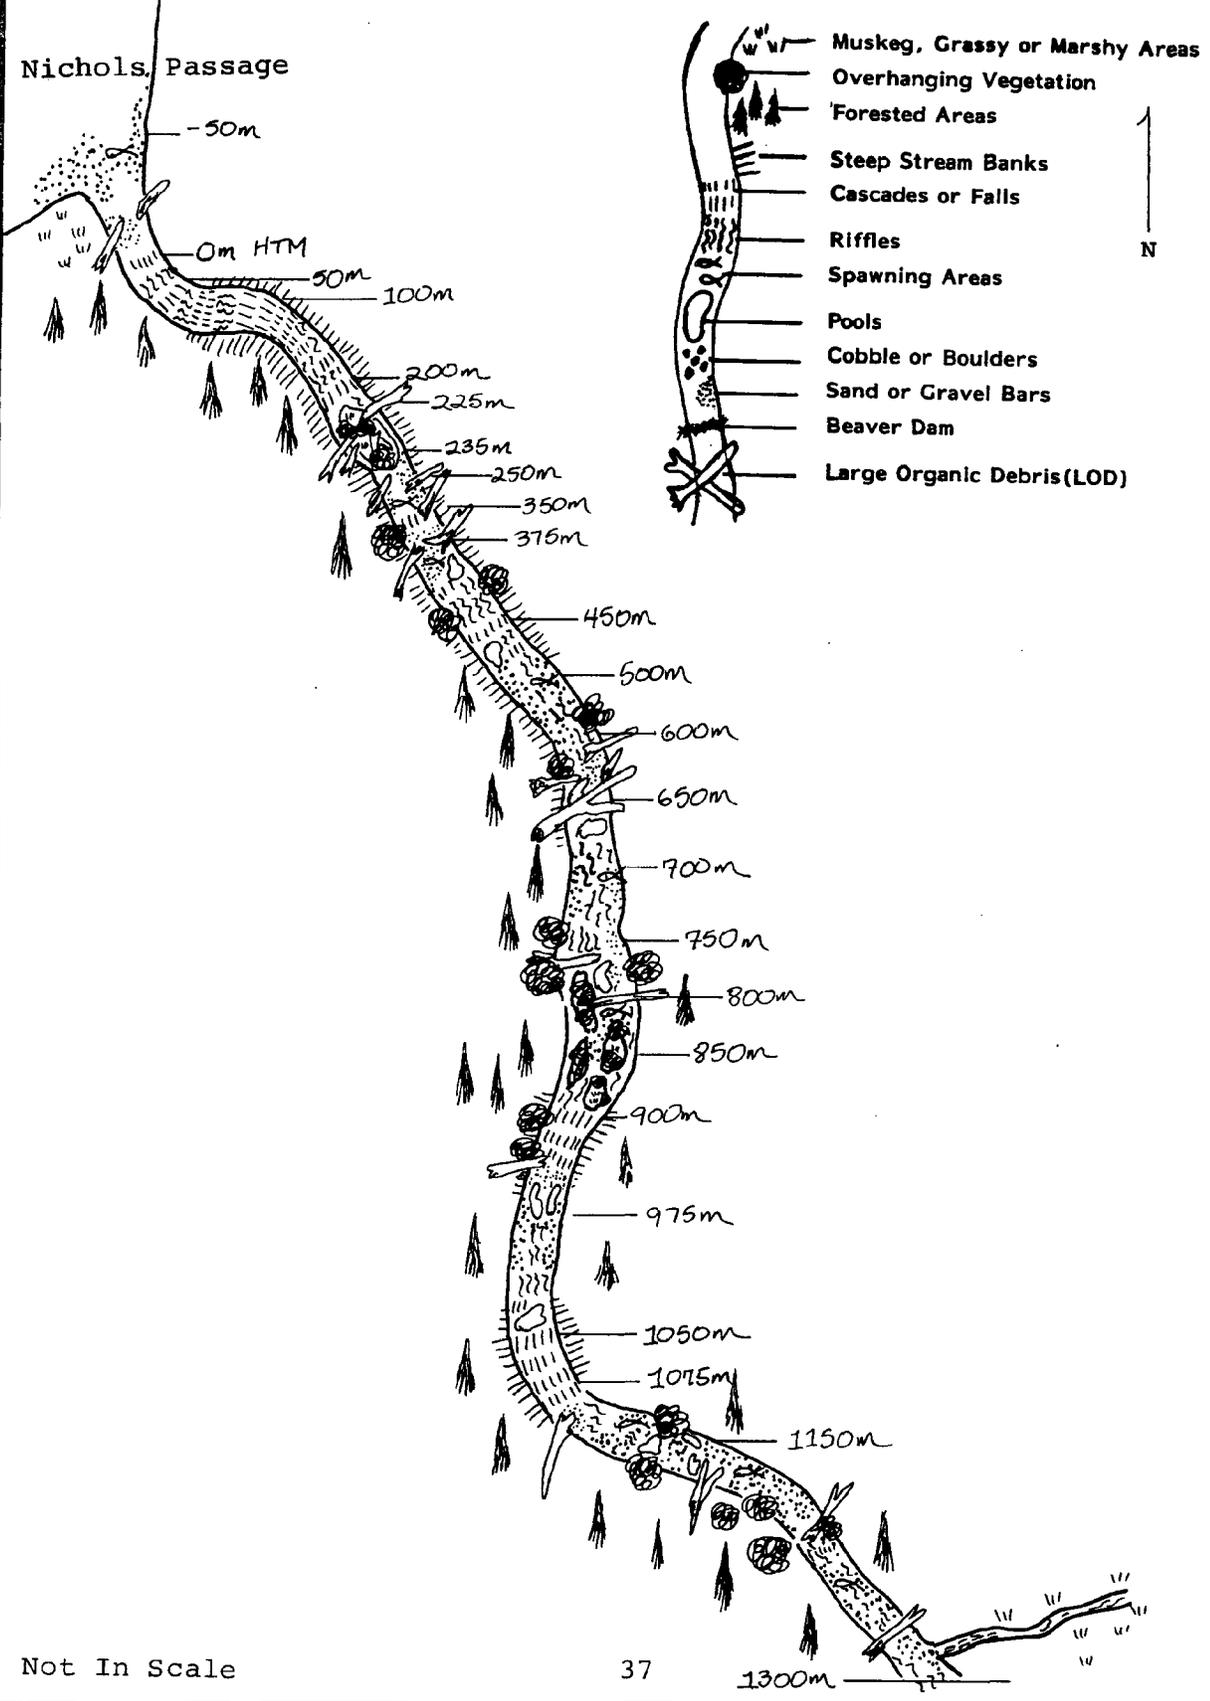

Recommended Escapement

12 spawning pairs of coho, 35 spawning pairs of chum, and 1400 spawning pairs of pinks (they probably all spawn below 900m, due to cascades).

Potential Production Summary

With the poor gravel quality, a 1.2% egg-fry survival rate is assumed. With the recommended escapements, approximately 500 pinks, 21 chums, and 8 coho could return to Annette Island from this creek.

Figure 4. NICHOLS PASSAGE CREEK II - Section 1

Not In Scale

NICHOLS PASSAGE CREEK II

Watershed No. 111-01

Stat. No. 101-28-003

-50m End of intertidal spawning area.

-50-0m Average Stream Width (ASW) = 4m, Average Stream Depth (ASD) = 0.7m, with 20% spawning gravels, 50% boulder, 30% large cobble; High Tide Mark (HTM) at 0m.

0-50m 100% bedrock; at 50m, 1m high falls (not a barrier).

50-100m 100% bedrock, moderate gradient, ASW = 2m, ASD = .22m; at 100m, 1 m high bedrock cascades.

100-200m 100% bedrock; 1.5m high bedrock cascade.

225m LOD blockage, 7m long pool created by it; ASW = 3m, ASD = .5m.

235m Gravels in bottom return (20% spawning area).

250-350m Good rearing habitat here, low gradient with LOD and gravel bars 5m long and 4m wide; bottom composition is 30% gravels, 10% clay with fines being prevalent, ASW = 3.5m.

350-375m Bottom composition, 60% small boulders, 30% cobble, 5% bedrock, less than 5% spawning area.

375-450m ASW = 3m, ASD = .15m, bottom is 75% spawning gravels.

450-500m Bedrock and boulders mainly, less than 5% spawning gravels.

500-650m ASW = 3.2m, ASD = .08m, 50% spawning gravels; deer tracks numerous here; 4.5 inch cut-throat trout seen at 600m.

650m Alot of LOD and pools here.

700m Pockets of gravel bars 5m long and 3m wide; however; gravel is flat and angular (poor quality).

750m Flood plain widens; creek runs through a gorge up to this point; alot of rearing habitat here.

800m Side channel.

850m Braids and flashy channels (not a well-defined channel); ASW = 2.5m, 50% spawning gravels.

500-900m Good rearing habitat, much area is available; at 900m, is a 1m falls, ASW = 2m and less than 5% gravels occur.

975-1050m ASW = 1.5m, increases to 30% gravels.

1050-1075m Rock cascades (not a barrier).

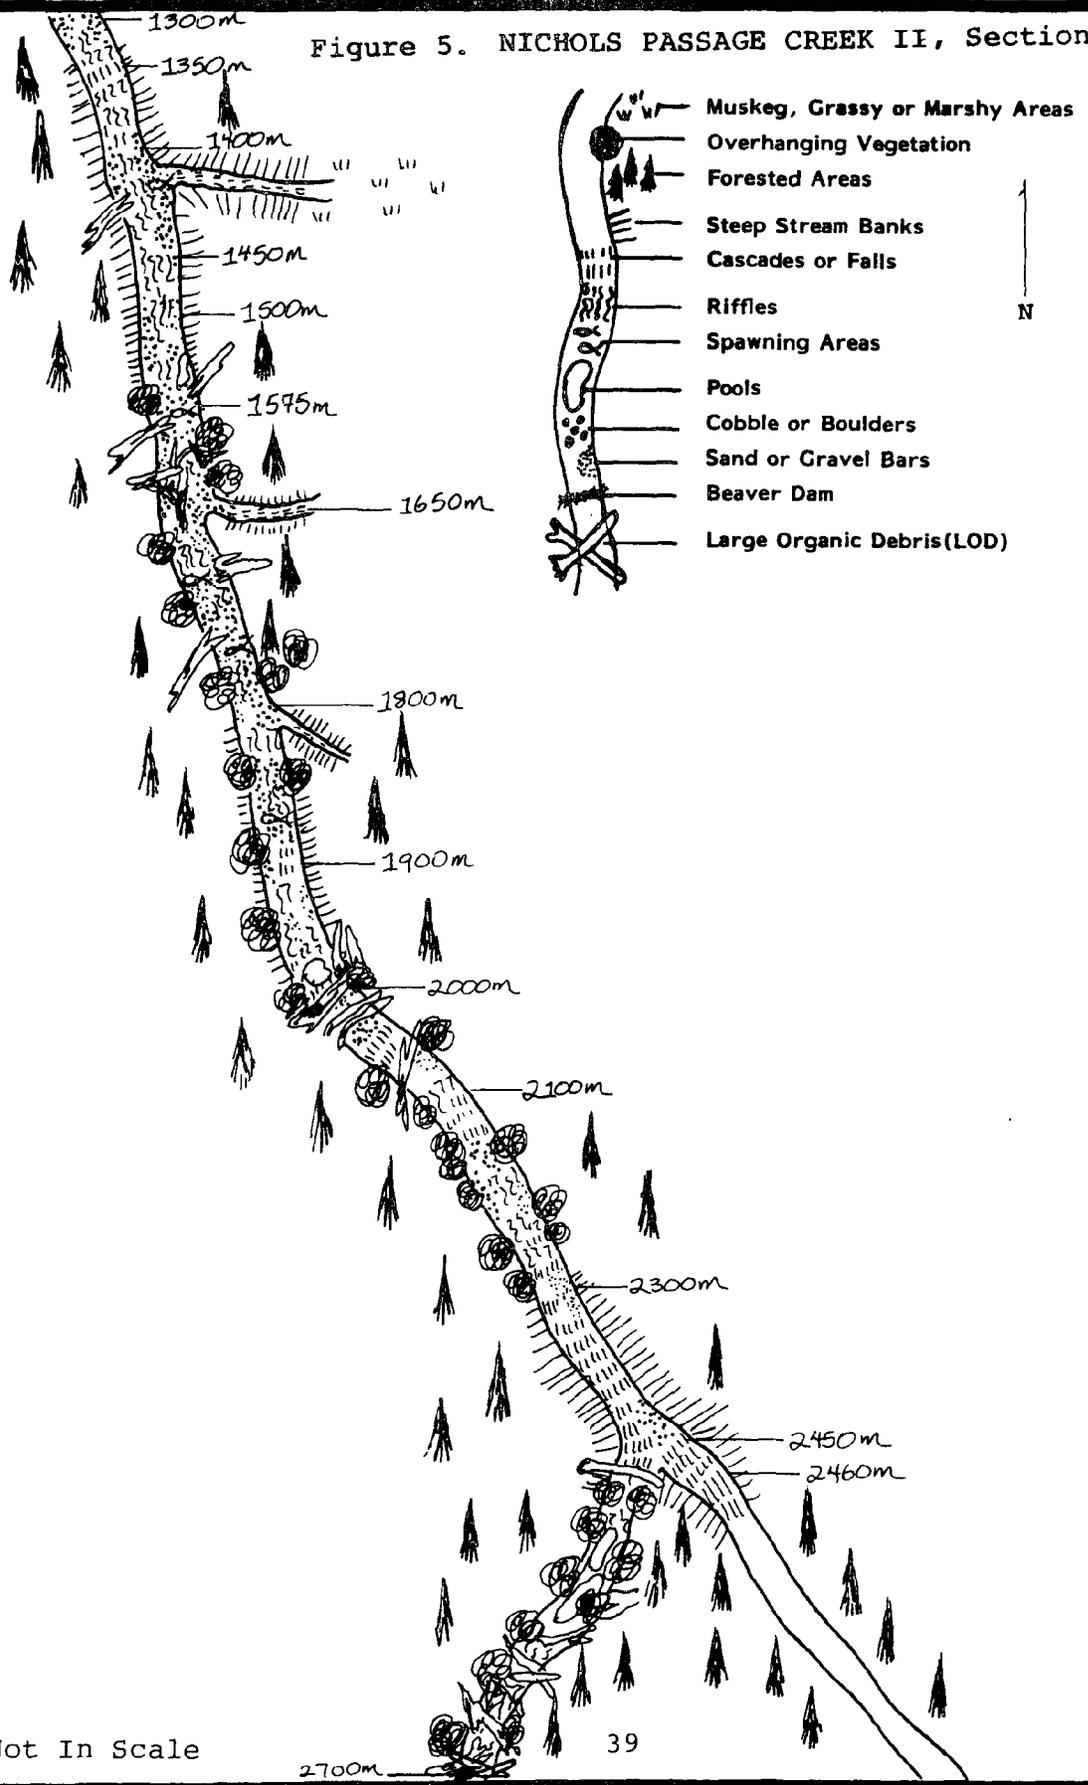

1075-1150m ASW = 2.0m, 70% spawning gravels.

1150-1300m ASW = 1.5m, 50% spawning gravels.

1300-1350m ASW = 1.5m, 20% spawning gravels; at 300m, a small tributary (.25 cfs flow) enters from muskeg.

Upper half of creek is bordered by old growth timber with little to no understory.

Figure 5. NICHOLS PASSAGE CREEK II, Section 2

Not In Scale

2700m

NICHOL PASSAGE CREEK II (CONTINUED)

1350m Bedrock riffle

1400m ASW = 1.5m, ASD = .07m, 30% spawning gravels above 1400m, a tributary enters draining muskeg with a bedrock bottom.

1450m Gravels less than 5% of bottom below 1450m, and 10% above.

1575m ASW = 1.5m, 50% spawning gravels.

1650-1800m ASW = 1.0m, 50% spawning gravels including some gravel bars, at 1650m, a .25 cfs tributary enters draining muskeg over bedrock.

1800-1900m At 1800m, .25 cfs tributary enters; 30% spawning gravels to 1900m.

1900m ASW = 1.5m, ASD = .06m, less than 5% gravels here.

2000m 1.5m diameter log and additional LOD straddles creek (not a barrier at higher flow), less than 5% gravels.

2000-2300m Less than 5% to 0% gravels, at 2300m, a gorge begins (not a barrier).

2450m Stream forks.

2460m North Fork, barrier falls - end of survey.

2450-2700m South Fork, choked with debris and bottom is mud and silt, no good spawning or rearing habitat here; at 2700m, debris barrier across creek.

Spawning Area:

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Nichols Passage Creek I	101-28-004	111-02
Stream Flows N.W., about 1.2 mi. long, into Nichols Pass.	Number A small lake, mountain slope run-off and springs	Geocode Timbered mountain and bedrock slopes.
Location 1850m above High Tide Mark (HTM)	Origin Possibly at 1075m and 1475m	Watershed Type --
Date Surveyed 6/17/81	Section Surveyed 1-2%, up to 30% in cascade	Barriers 6 cfs --
Ave. Gradient Bedrock and heavily vegetated of dirt and rock banks	Flow / Range 6 cfs --	Ave. Velocity/Range 1.5 fps / 1-2 fps
Streambank Composition	Stability	Tributaries None
		Stage 2.5m --
		Flood Height .15m --
		Ave. Width/Range None
		Ave. Depth/Range None

Water Quality

10 Above HTM	11.7C	14C	--	Clear	Light Amber	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO2
--	--	--	--	--	--	--	--
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

40% bedrock, 10% boulders, 10% rubble, 10% cobble, 20% gravel, 5% pebble, 5% sand with trace silt.

Overall Stream Bottom Composition

Beaches are mostly gravel with some cobble, pebbles, sand and silt. Relatively clean gravel - limited compaction.

Gravel Compaction

Some available on gravel bars - approximately 55m² area available.

Spawning Area Available Above High Tide Mark (HTM)

None

Intertidal Spawning Area

Rearing Area

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
--	--	--

Available Cover

Aquatic Invertebrates/Available Food Source

Aquatic Vegetation

Devil's club, salmonberry, currant with skunk cabbage and ferns occasionally; timber is hemlock, spruce, and cedar.

Terrestrial Vegetation

65% from topography and some riparian vegetation.

Shading

Good coho rearing habitat of moderate abundance.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Limited production of salmon, coho, and cutthroat use creek and possibly pink and chum if they can get over cascades.

Use by Fish

Very little, if any, commercial fishing outside mouth, trap is nearby.

Use by Fishermen

Wildlife Present

Comments and Recommendations

In general, the creek has little accessible spawning and rearing area for anadromous salmonids and because of the channel instability, spawning and rearing area present is questionable; okay for trout.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/17/81	Cutthroat	Fry 50-180mm	Over 50	--	

Survey(s) and Dates Conducted

C. Huntington, 6/17/81

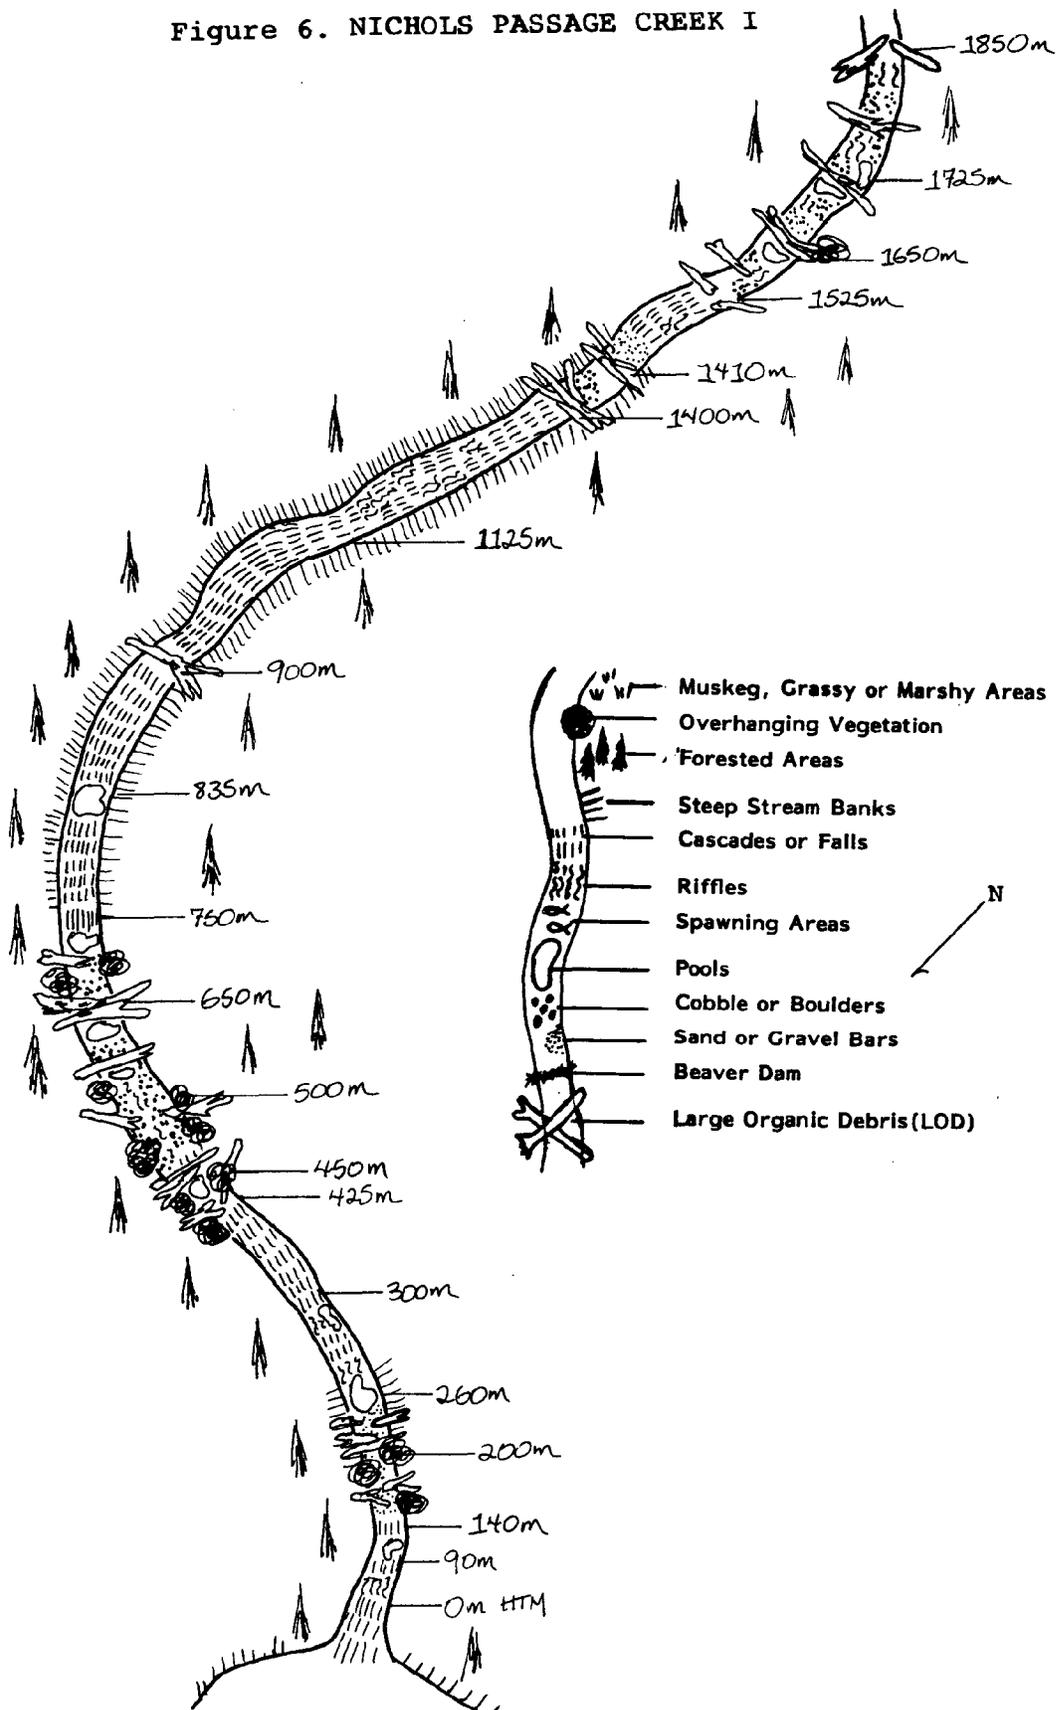

Recommended Escapement

Due to the cascades and inaccessibility, pinks and chum probably cannot or do not utilize this creek. There is only enough gravels for about 5 coho spawning pairs, with a moderate amount of rearing area available.

Potential Production Summary

Due to the fair quality gravels, a 10% egg-fry survival rate is assumed and approximately 28 adult coho could be expected to return to Annette Island from this creek.

Figure 6. NICHOLS PASSAGE CREEK I

Not In Scale

Nichols Passage

NICHOLS PASSAGE CREEK I

Watershed No. 111-02
Stat. No. 101-28-004

0m High Tide Mark (HTM); creek flows over a 10m long 1.2m passable cascade.

90m 5m Cascade (30° gradient).

140-260m 1.3m Cascade with a .7m deep plunge pool; above 140m, gradient drops and good rearing habitat (alot of LOD and overhanging vegetation); at 200m is a large 2m deep pool; at 260m is an 8m long pool with bedrock walls.

270-280m Cascading channel over bedrock.

300-330m Cascading channel with possible barrier; above 330m, cascades may become a velocity barrier.

425m Gradient drops again to 1-2%.

450m Good coho rearing area, alot of LOD and side channels.

500m Wide gravel bars and flood plain here with undercut banks and root tangles.

650m Debris jam with gravel above.

750-825m .8m falls at 750 m with bedrock and cascades to 825m.

835m Huge pool averaging 1.5m (2m at deepest point), 4 x 6m in area.

900m Debris jam.

875-1400m Bedrock and boulders with a possible barrier cascade in a gorge at 1075m.

1400m Small debris jam with gravels piled up behind it.

1410-1450m Behind debris jam is 35m² spawning area.

1450-1525m Bedrock and boulders with a 3m high possible barrier cascade at 1475m.

1525-1650m Gradient lowers to 2%; debris jam and LOD at 1650m.

1725m LOD moderate; undercut banks and root tangles here; some fines piled behind debris jams - little to no spawning area.

1850m End of survey; it is unlikely that salmon even get up here.

Spawning Area: Limited. Approximately 50m² is available and is of marginal quality.

No intertidal area. 44

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Japan Creek II		101-28-005		109-01	
Stream Flows S.W. into Japan Bay - .5 mi long.		Number Run -off from Round Mountain		Geocode Timbered mountain slopes - (84 acres in area).

Trace (6/8/72)		10/5 ppm (6/8/72)		89.8 ppm (6/8/72)	
Total Alkalinity		Total Hardness		Dissolved Solids	
				Other/Overall	
				Resistivity = 4810 ohm/cm ³ (6/8/72)	

Spawning Area

Mainly boulder, bedrock, and gravels (50% bedrock, 30% cobble and boulder, 20% gravels (poor quality)).

Overall Stream Bottom Composition

Lots of angular gravels.
Gravel Compaction

Limited - None from 100-150m (bedrock); less than 50m² total available.

Spawning Area Available Above High Tide Mark (HTM)

Gravels mixed with too many fines - no spawning area.

Intertidal Spawning Area

Rearing Area

Mainly riffle - a couple pools due to LOD and falls. --

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
-----------------------------------	-----------------------	----------------------

Limited - banks are steep (10 ft high average), but some LOD is present.

Available Cover

Moderately abundant - ephemeroptera and Odonata observed.

Aquatic Invertebrates/Available Food Source

Scarce

Aquatic Vegetation

Sparse - some ferns, salmonberry, currant, and skunk cabbage.

Terrestrial Vegetation

90% - 80% from canopy and 10% from banks and overhanging vegetation.

Shading

None to speak of.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks are known to spawn below falls.

Use by Fish

No known use by fishermen.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Minor stream - limited production - no improvements recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/7/72	None Seen	--	--	--	--
6/7/81	None Seen	--	--	--	--

Survey(s) and Dates Conducted

E. Biggs, J. Yuska, 6/7/81, and USFWS, 6/8/72

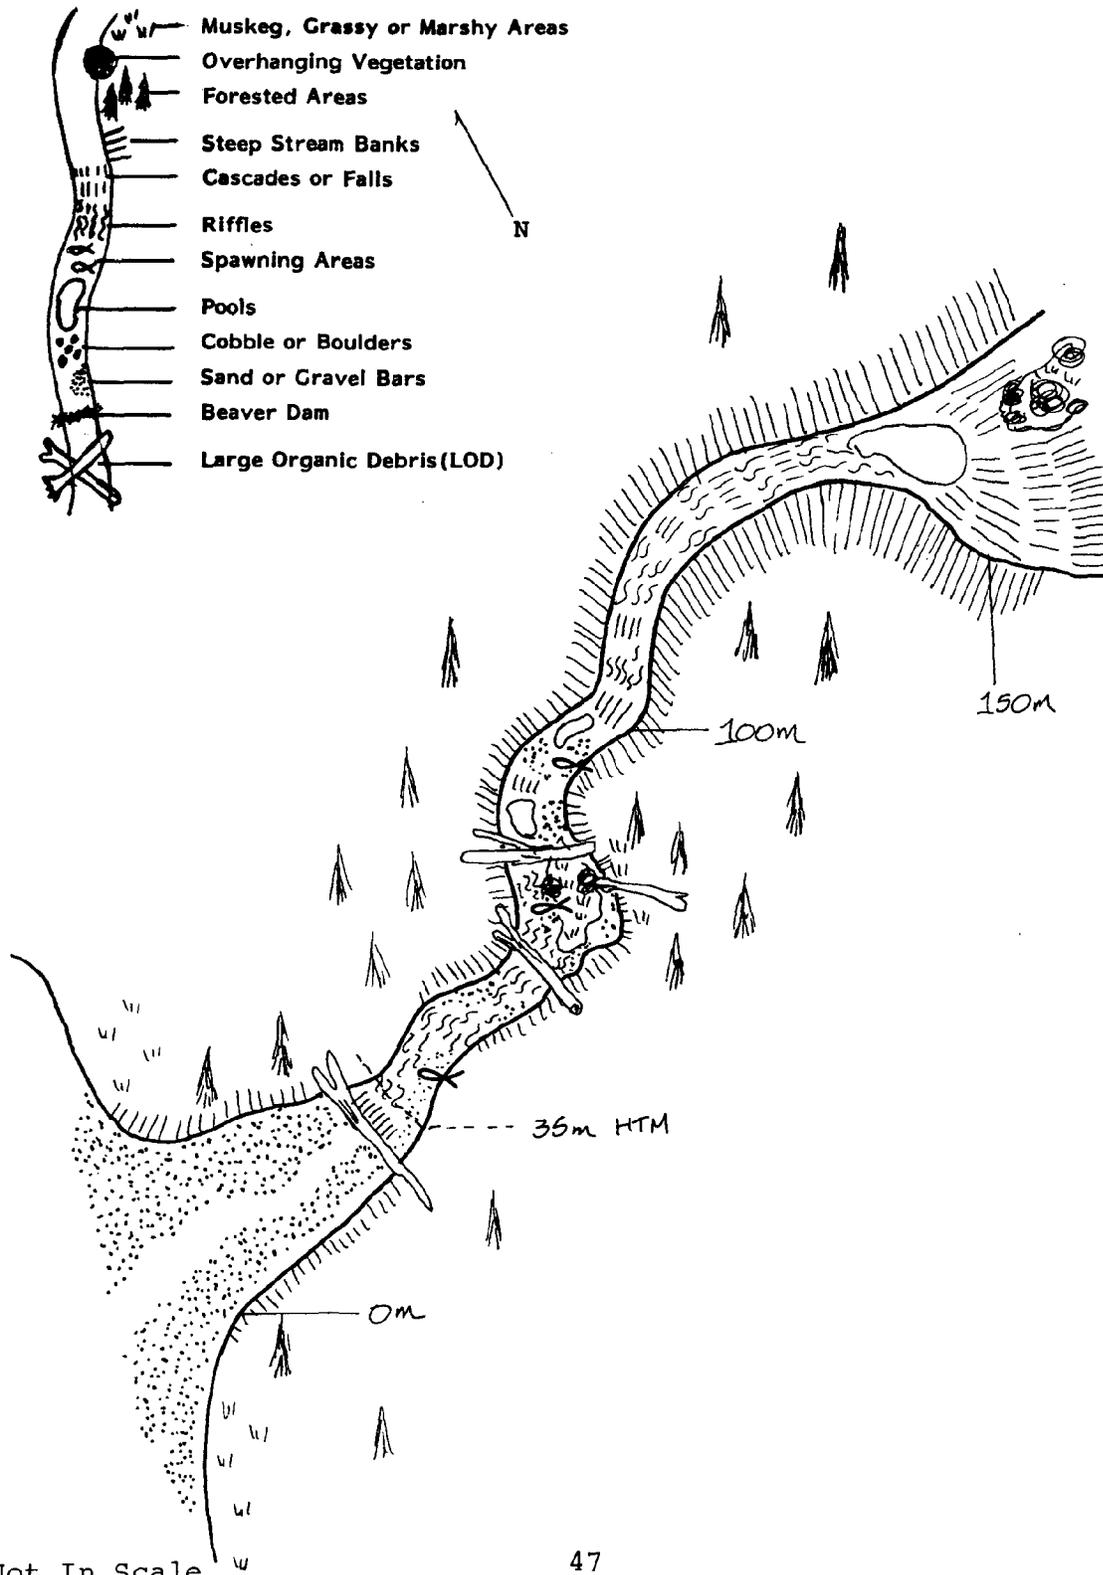

Recommended Escapement

Probably only pinks utilize this creek if any salmon utilize it at all, and only 83 spawning pairs are recommended.

Potential Production Summary

The gravels are angular, and the creek flashy, therefore, only a 1.2% egg-fry survival rate is assumed. Therefore, approximately 30 pinks would return to Annette Island from this creek.

Figure 7. JAPAN CREEK II

JAPAN CREEK II

Watershed No. 109-01
Stat. No. 101-28-005

0m	Intertidal area is mostly sand and fines mixed with gravel and pebbles, not usable for spawning.
10m	High Tide Mark (HTM), Average Stream Width = 2m, Average Stream Depth = .15m.
100m	Bedrock and boulder to falls, below 100m, some LOD and pools occur.
150m	30m barrier falls.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Japan Creek I		101-28-006	108-01
Stream		Number	Geocode
Flows W. in Japan Bay - about .5 mi long.		Mountain run-off and seepage	Timbered mountain slopes (39 acres in area).

--	9.5C	9.0C	5.5
Sample Site	Temp.-Air	Temp.-Water	Ph
Trace (6/8/72)	15.0 ppm (6/8/72)	Total = 11.0 ppm (6/8/72)	Resistivity = 585,122 ohm/cm ³ (6/8/72)
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall
--	--	--	Alot of organic matter near beaver dams.

Spawning Area

20% bedrock, 20% rubble and boulders, 30% gravels, 30% fine gravels, sand and silt.

Overall Stream Bottom Composition

Some angular shales and fines
mixed with gravel.
Gravel Compaction

Limited to about 39m² - marginal quality gravels.

Spawning Area Available Above High Tide Mark (HTM)

Limited to about 37.5m² - marginal quality gravels.

Intertidal Spawning Area

Rearing Area

Pool in 40% of creek, riffles in 20%.

Large pond at 475m is 1.5 x 15m

Pool/Riffle Frequency (P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Undercut banks and root wads, pools behind alot of debris jams with LOD (old beaver dams in upper section of logs).

Available Cover

Scarce - diptera

Aquatic Invertebrates/Available Food Source

Scarce - some moss on rocks.

Aquatic Vegetation

Moss, salmonberry, currant, fern, alder - timber is mainly hemlock.

Terrestrial Vegetation

Up to 90% in some areas; 70% average - 60% due to timber, 10% due to riparian vegetation.

Shading

Some coho rearing habitat is available, but is limited due to small size of stream.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pink and chum use creek.

Use by Fish

Deer hunting and some subsistence fishing, low fishing pressure.

Use by Fishermen

Wildlife Present

Alot of beaver activity.

Comments and Recommendations

The creek has gone through some changes, a couple of beaver dams have been washed out (beavers trapped out?)

An okay stream for pink and chum; although coho could rear here also - limited by size of creek.

No improvements are recommended, since it is a nursery stream and does have some spawning area, logging could have detrimental affects on stream.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/8/72	Unidentified salmonid	Fry	--	--	Below second beaver dam.
8/15/80	Mostly pinks with chum	Adults	1500	--	Aerial count, fish at creek mouth.
6/7/81	None observed	--	--	--	--
9/1/81	Pink	Adults	100	--	Aerial count, fish at creek mouth.

Survey(s) and Dates Conducted

E. Biggs, J. Yuska, 6/7/81 and USFWS, 6/8/72

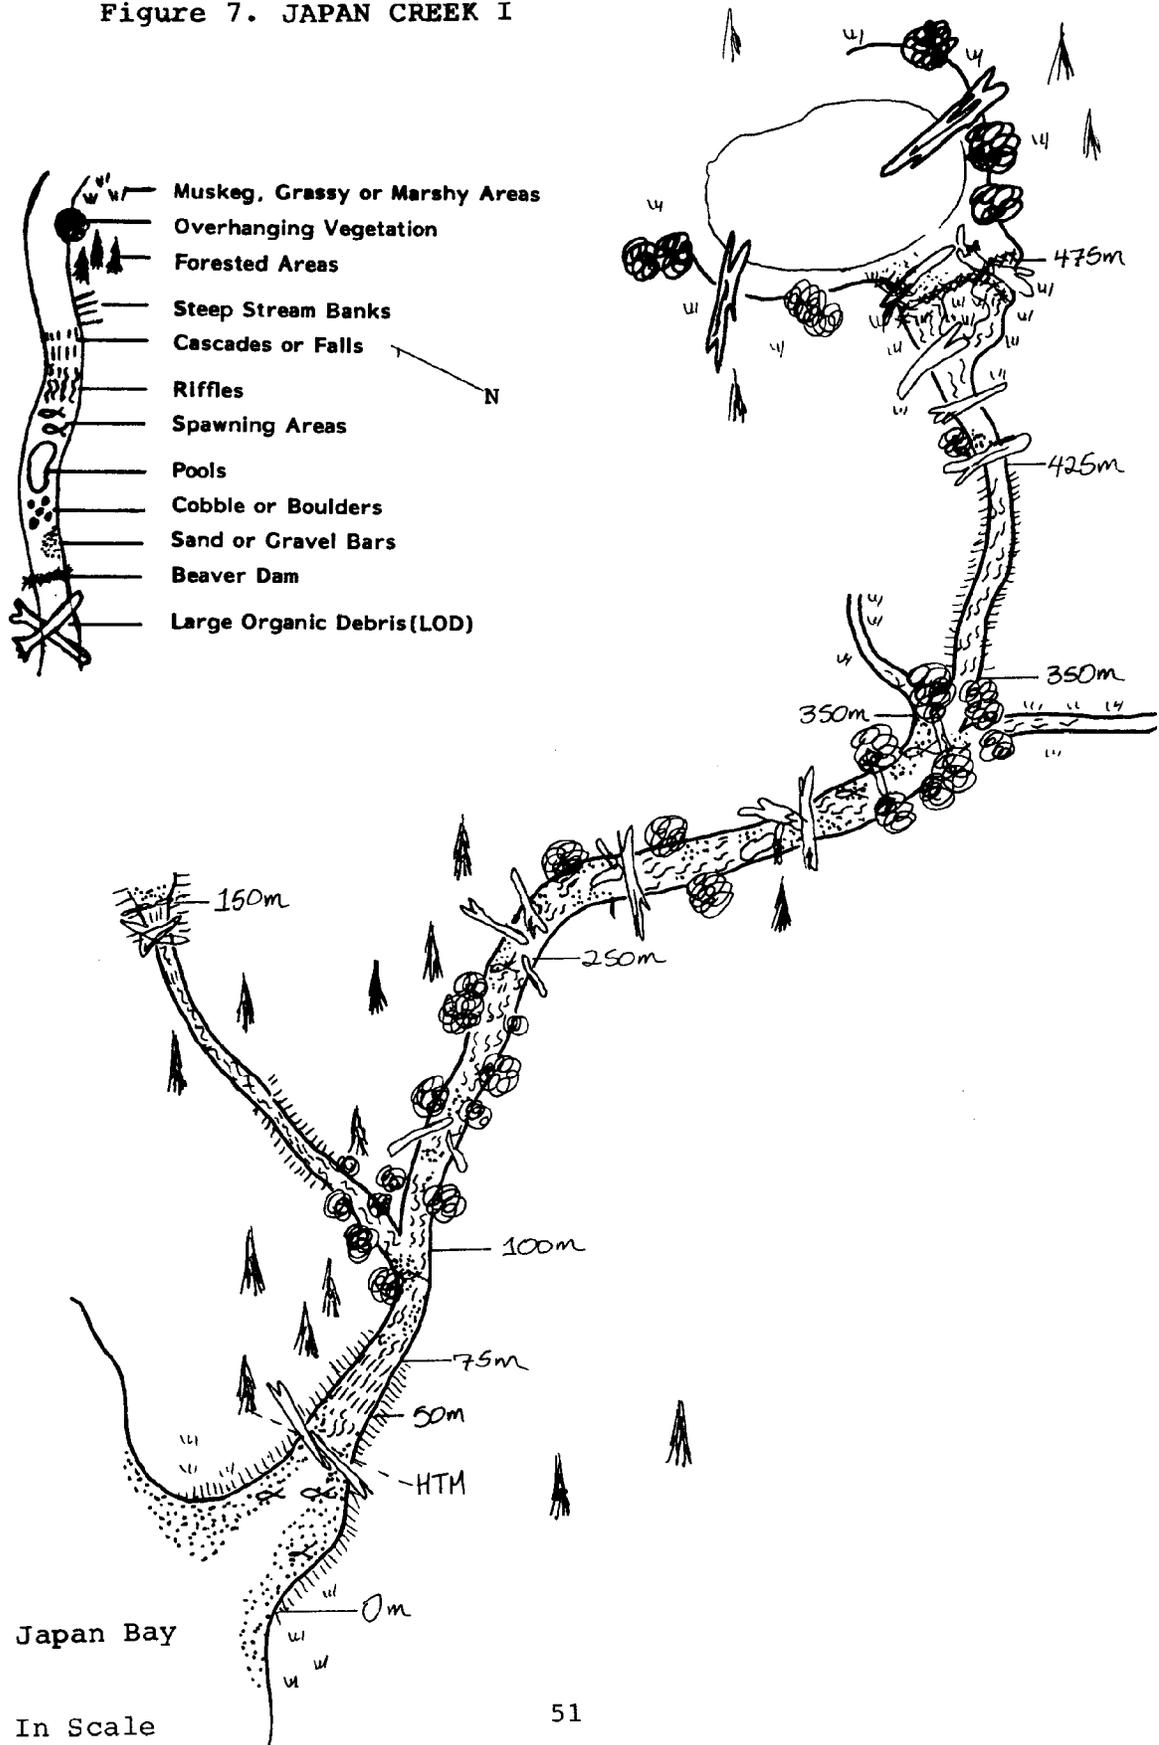

Recommended Escapement

Probably only pink and chum utilize this creek. Recommended escapement is only about 130 pinks spawning pairs and 8 chum spawning pairs.

Potential Production Summary

Potential production from this creek, assuming a 10% egg-fry survival rate (fair quality gravels), is 3860 pinks and 40 chum returning to Annette Island.

Figure 7. JAPAN CREEK I

Not In Scale

JAPAN CREEK I

Watershed No. 108-01
Stat. No. 1010-28-006

- 0m Beginning of a small Estuary, Average Stream Width (ASW) = 1.5m, Average Stream Depth (ASD) = .08m, about 50% good spawning gravels (37.5m² total area).
- 30m High Tide Mark (HTM), LOD here, few gravels mixed with boulders to 50m.
- 50-75m Bedrock Cascade
- 75-100m At 75m, gravels begin again, tributary centers at 100m, tributary has ASW = 1.0m, ASD = .05m, .4 cfs flow - okay coho rearing habitat, except gradient is moderate to 150m in tributary where stream is clogged with debris and gradient increases.
- 75-250m ASW = 1.2m, 10% spawning gravels (21m² area)
- 250-350m Above 250m bottom has alot of fine sand mixed with gravels, alot of LOD in channel, a lower stream velocity and gradient with good rearing habitat.
- 350m Two tributaries come in, main channel flow is reduced by one-half; stream banks are clay, and there is a thick alder canopy; gravels here are smaller, but still usable for spawning - during high flow more gravel on banks is available.
- 350-425m Large debris jam blocks fish except during high flow at 425m, ASW = .8m, ASD = .05m, 10% spawning gravels (6m² area).
- 475m Abandoned beaver dam, a fish barrier - flow is a trickle and dam is wide, 1.5m high, heavy LOD influence from 425m.
- Spawning Area: Limited. Intertidal area is 37.5m².
Freshwater area is approximately 39m².

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Hemlock Creek - North Fork		101-28-009	107-01	
Stream		Number	Geocode	
Fork of Hemlock Creek		Same as Hemlock	Same as Hemlock	
Location		Origin	Watershed Type	
6/5/81	700m from Fork	Falls at end (1310m)	Moderate	--
Date Surveyed	Section Surveyed	Barriers	Stage	Flood Height
--	25 cfs (6/23/76)	1 fps --	2m --	.20m
Ave. Gradient	Flow / Range	Ave. Velocity/Range	Ave. Width/Range	Ave. Depth/Range
Soil and dirt stabilized by heavy vegetation.		Stable	None	
Streambank Composition		/ Stability	Tributaries	

Water Quality

Above Fork	11.1 C	11 C	6.8 (6/23/76)	Clear	None	Light Amber	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity		Color	D.O.	CO₂
--	--	--	--	Same as Hemlock.				
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall					

Spawning Area

15% spawning gravels.

Overall Stream Bottom Composition

Limited - good gravels.
Gravel Compaction

183m² area - good quality gravels.

Spawning Area Available Above High Tide Mark (HTM)

Not applicable.

Intertidal Spawning Area

Rearing Area

A few pools (small) - mostly riffles and runs .75m -- -- --

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
LOD (some clue to logging) and overhanging riparian vegetation.		

Available Cover

Scarce

Aquatic Invertebrates/Available Food Source

Scarce

Aquatic Vegetation

Thick riparian vegetation, salmonberry, devil's club, currant under spruce - hemlock timber.

Terrestrial Vegetation

80-90% due to overhanging vegetation.

Shading

Extensive in fork - good steelhead, trout, and coho spawning and rearing habitat; good cover available.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Coho, trout, pink and chum use it for spawning and rearing.

Use by Fish

None known.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

The Fork is where most of the good rearing area available in Hemlock Creek exists. A significant amount of spawning area exists also - logging has added LOD and cover, increasing the rearing area in creek - detrimental affects are minimal.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
------	---------	------	--------------	------	----------

(See form on Hemlock Main Channel.)

Survey(s) and Dates Conducted

C. Huntington. 6/5/81 and USFWS, 6/23/76

Recommended Escapement

Coho and chum probably utilize the north fork and due to the limited coho rearing area, only 10 coho spawning pairs and 7 chum pairs are recommended for escapement.

Potential Production Summary

Given the above escapements with an assumed 10% egg-fry survival rate, 56 coho and 35 chum can be expected to return as a result of production from this fork.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

gravels. Minimal - high quality gravels
Gravel Compaction

Approximately 300m² area - most of which occurs just above the weir.

Spawning Area Available Above High Tide Mark (HTM)

1650m² - excellent quality spawning channel.

Intertidal Spawning Area

Rearing Area

Some deep pools formed by LOD, mainly riffles and runs. .65m One pool was 60m long.

Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range

Much LOD - some due to logging; no undercuts because of rock banks.

Available Cover

Scarce - some intertidally.

Aquatic Invertebrates/Available Food Source

Some algae and moss covered boulders.

Aquatic Vegetation

Grass and sedges intertidally with canopy of hemlock and spruce - thick riparian vegetation begins at 610m.

Terrestrial Vegetation Intertidal area - 5% due to banks and some canopy; above HTM 60% due to banks, overhanging vegetation, and canopy.

Shading

Some rearing area exists under and around LOD, otherwise, limited. (Channel is mainly riffles and runs.)

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Chum, coho, pink and cutthroat use creek and possibly steelhead.

Use by Fish

Subsistence fishing (especially when logging camp was operating) and egg take for hatchery - closed to

Use by Fishermen commercial fishing.

Wildlife Present

--

Comments and Recommendations

Excellent pink and chum spawning areas (they mainly use the lower areas); logging affects have improved stream production quality if anything, due to increase in LOD - detrimental affects are minimal. Hemlock is a major salmon producing stream on Annette Island. The lack of coho fry is unsettling, the adults

may have been fished out, so stream should be checked in the fall for presence of coho spawners.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/11/67	Pinks	Adults	2200		USFWS Escapement Estimate

1975	Pink	Adults	18,874		USFWS Escapement Estimate
1976	Pink	Adults	21,919		USFWS Escapement Estimate
8/15/80	Pink	Adults	1000		Weir Count
	Chum	Adults	20		Weir Count
8/18/80	Pinks mainly (mixed with chum)	Adults	20		Approximately 1% chums; salmon count in creek above and below weir.
9/1/81	Pink	Adults	100		Outside creek mouth (aerial count)
9/5-10/4-1981	Pinks	Adults	2700 (2000 put above Weir)		Weir Count Hatchery egg take
	Chums	Adults	420 (100 put above Weir)		(2000 pinks and 100 chum were allowed to spawn naturally.
	Coho	Adults	10		

Survey(s) and Dates Conducted

E. Biggs, J. Yuska, C. Huntington, 6/5/81, and USFWS, 5/8/72

Recommended Escapement

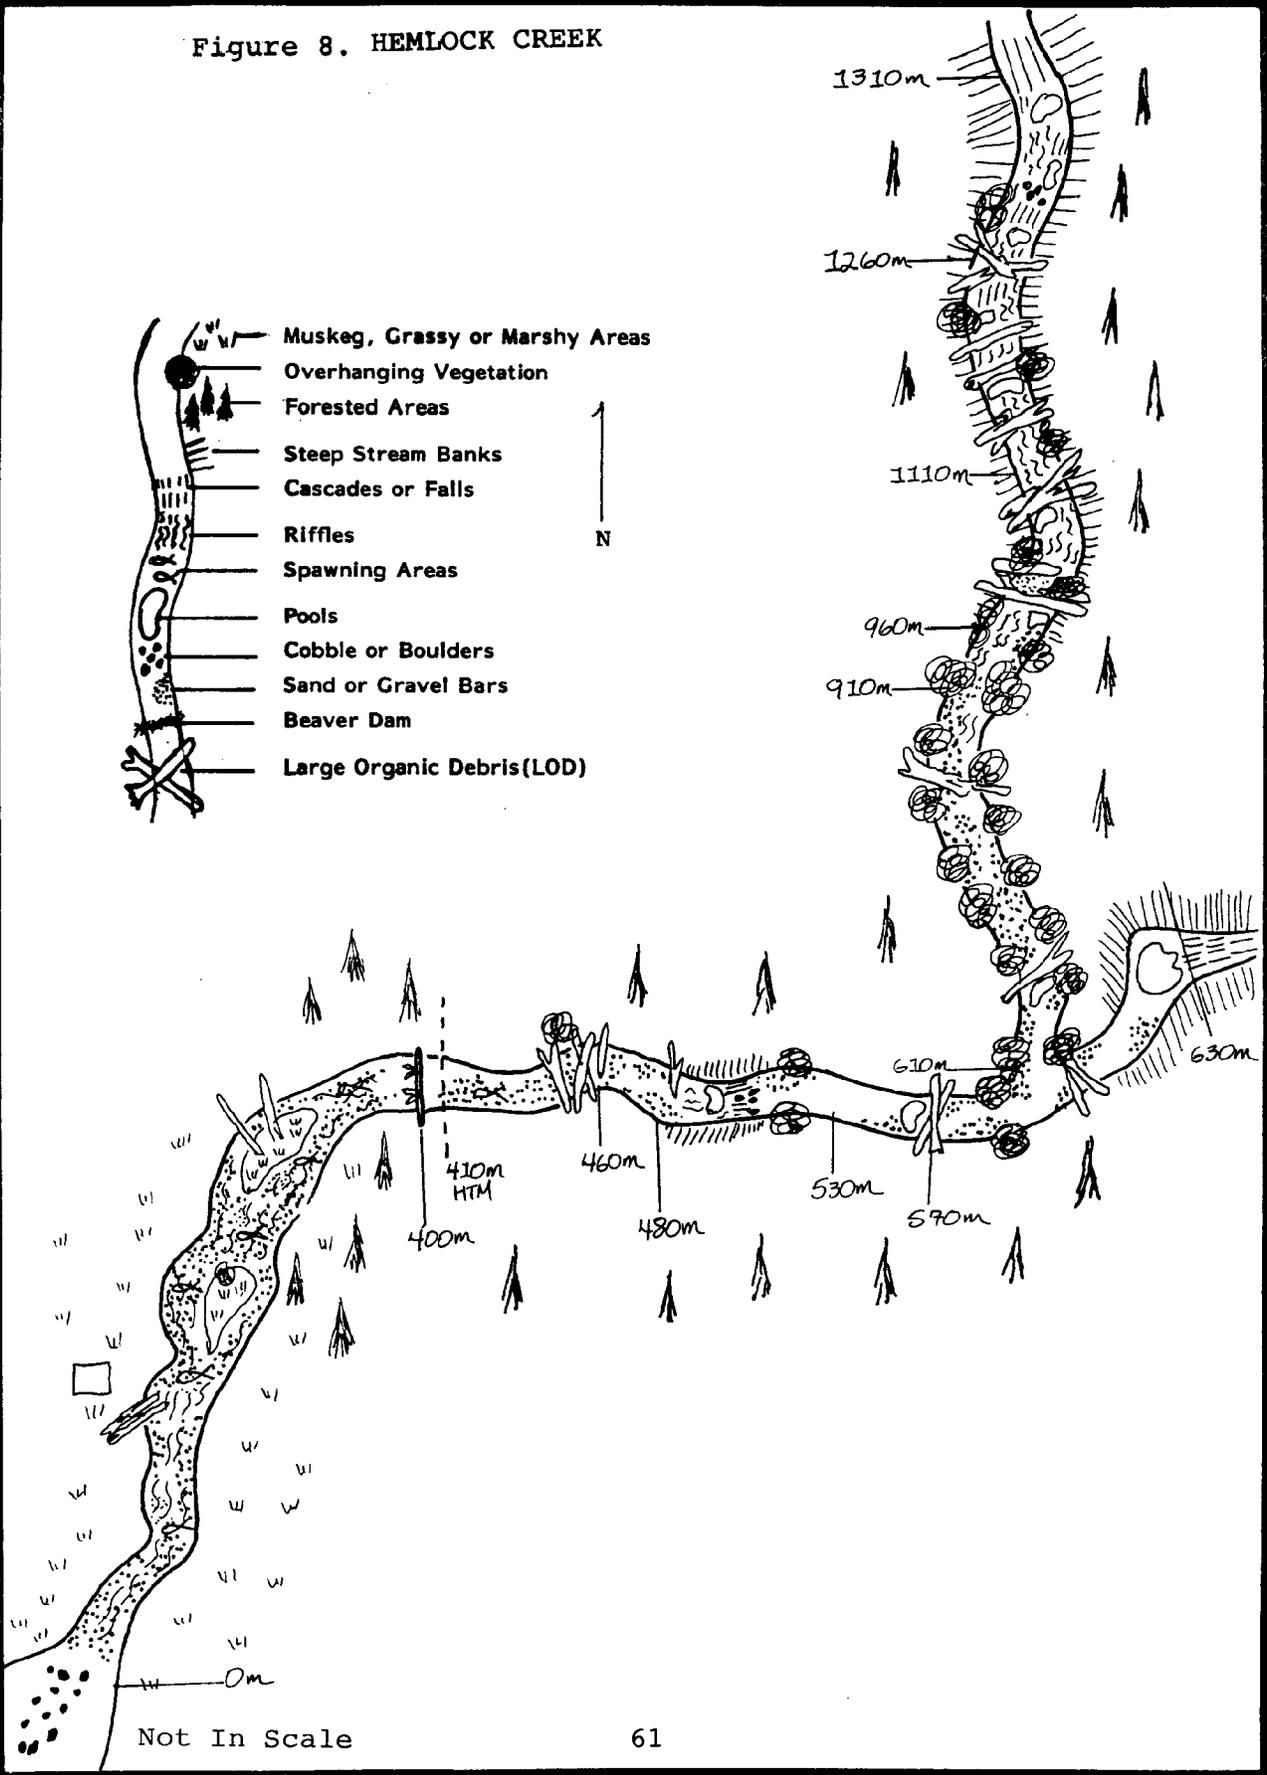

Only pinks and chum utilize the intertidal area, which is extensive, coho probably only utilize the North Fork (see previous stream form). It is recommended that approximately 3000 pink spawning pairs and 170 chum spawning pairs be allowed to escape and spawn in this creek.

Potential Production Summary

Approximatley 8900 pinks and 849 chum could be expected to return to Annette Island resulting from production in this main channel of Hemlock Creek (gravels are good quality so a 10% egg-fry survival rate is assumed).

Not In Scale

HEMLOCK CREEK

Watershed No. 107-01
 (North Fork)
 107-02 (Main Channel)
 Stat. No. 101-28-009

0m Creek mouth, bottom is boulders and bedrock.

0-410m 20% spawning gravels, Weir at 400m, High Tide Mark (HTM) at 410m.

410-460m 20% spawning gravels, large log pile at 460m (not a barrier).

0-460m From 0m, Average Stream Width (ASW) = 20m, Average Stream Depth (ASD) = .25m.

460-530m Heavy LOD influence, Average Stream Velocity = .08 fps, ASW = 5m, 10% spawning gravels, evidence of gravel bars spawnable at high flows. At 480m, gravel is smaller, but better quality than at 460m.

530-570m ASW = 5.5m, 5% spawning gravels.

570-610m LOD pile with 6m long pool at 570m. ASW = 5.5m, 20% spawning gravels.

610-630m In South Fork, ASW = 5.5m, ASD = .3m, bottom is large gravels and cobbles with 10% spawning gravels. Barrier falls at 630m.

610-910m In North Fork, ASW = 2.5-3m, ASD = .15m, with 20% spawning gravels, rearing habitat is okay, not excellent - stream is more like a spawning channel.

910-960m Less gravels, some pools and riffles here.

960-1110 ASW = 1.75m, ASD = .25m, many boulders in channels with 5% spawning gravel. Good rearing habitat with alot of LOD, pools and riffles. Creek begins to run through a gorge.

1110-1260m Gorge becomes steeper, stream gradient increases and stream bottom is filled with moss covered boulders. No spawning or rearing area.

1310m Barrier Falls.

Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall		on next sheet.	

Spawning Area

Mainly boulders, cobble, rubble and bedrock.

Overall Stream Bottom Composition

Less than 2% of creek is spawnable; 90m² total available at best. Minimal Gravel Compaction

Spawning Area Available Above High Tide Mark (HTM)

At best 100m² is available - mainly mixed in with cobble and boulders.

Intertidal Spawning Area

Rearing Area

Pools formed by falls and boulders - they are small and sparse.

Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range

Very little - little overhanging vegetation or undercut banks, limited LOD.

Available Cover

Sparse - a few caddisflies, mayflies.

Aquatic Invertebrates/Available Food Source

Alot of algal growth on rocks.

Aquatic Vegetation

Not much overhanging vegetation - but shrubs and stunted trees are numerous.

Terrestrial Vegetation

Channel relatively open - 10% shading due to canopy.

Shading

Limited - probably not utilized by salmonids for rearing.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks, chum, coho, sockeye and dolly varden migrate through the creek.

Use by Fish

Heavy subsistence fishing (dipnetting and beach seining) and fly fishing.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Recommend strict regulations regarding subsistence fishing - escapements are much lower than they

could be (for potential area). Salmon probably only use creek for migration to lake.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/10/65	Unidentified	Adult	1700	--	Ball of fish outside mouth of creek (aerial creek).
8/26/75	Sockeye	Adult	1	--	In upper creeks.
10/6/75	Sockeye	Adult	49	--	In upper creeks.
7/30-8/15/80	Sockeye	Adults	40	--	In main creek.
6/6/81	None	--	--	--	--
9/19/81	Sockeye	Adults	19	3	In upper creeks.

Additional Water Quality Data:

Flow: 7/19/79 - 2.74 cfs (questionable), 8/21/79 - 7.20 cfs (questionable),
9/21/79 - 129.62 cfs (questionable), 8/7/73 - 19 cfs.

Water Temp: 7/19/79 - 19.5C, 8/20/79 - 20.5C 8/21/79 - 19.0C, 9/21/79 - 14.0C, 8/17/80, 16C -
stream, 17C lake.

D.O.: 7/19/79 - 10.0 ppm, 8/20/79 - 8.6 ppm, 9/21/79 - 9.7 ppm.

Conductivity: 7/19/79 - 16.5 ohm/cm², 8/20/79 - 18.0 ohm/cm², 9/21/79 - 32.0 ohm/cm²

Survey(s) and Dates Conducted

C. Huntington, J. Yuska, E. Biggs, 6/6/81; USFWS, 6/8/72 and 8/7/73; Pacific Rim Planners, Inc., 7-9/79

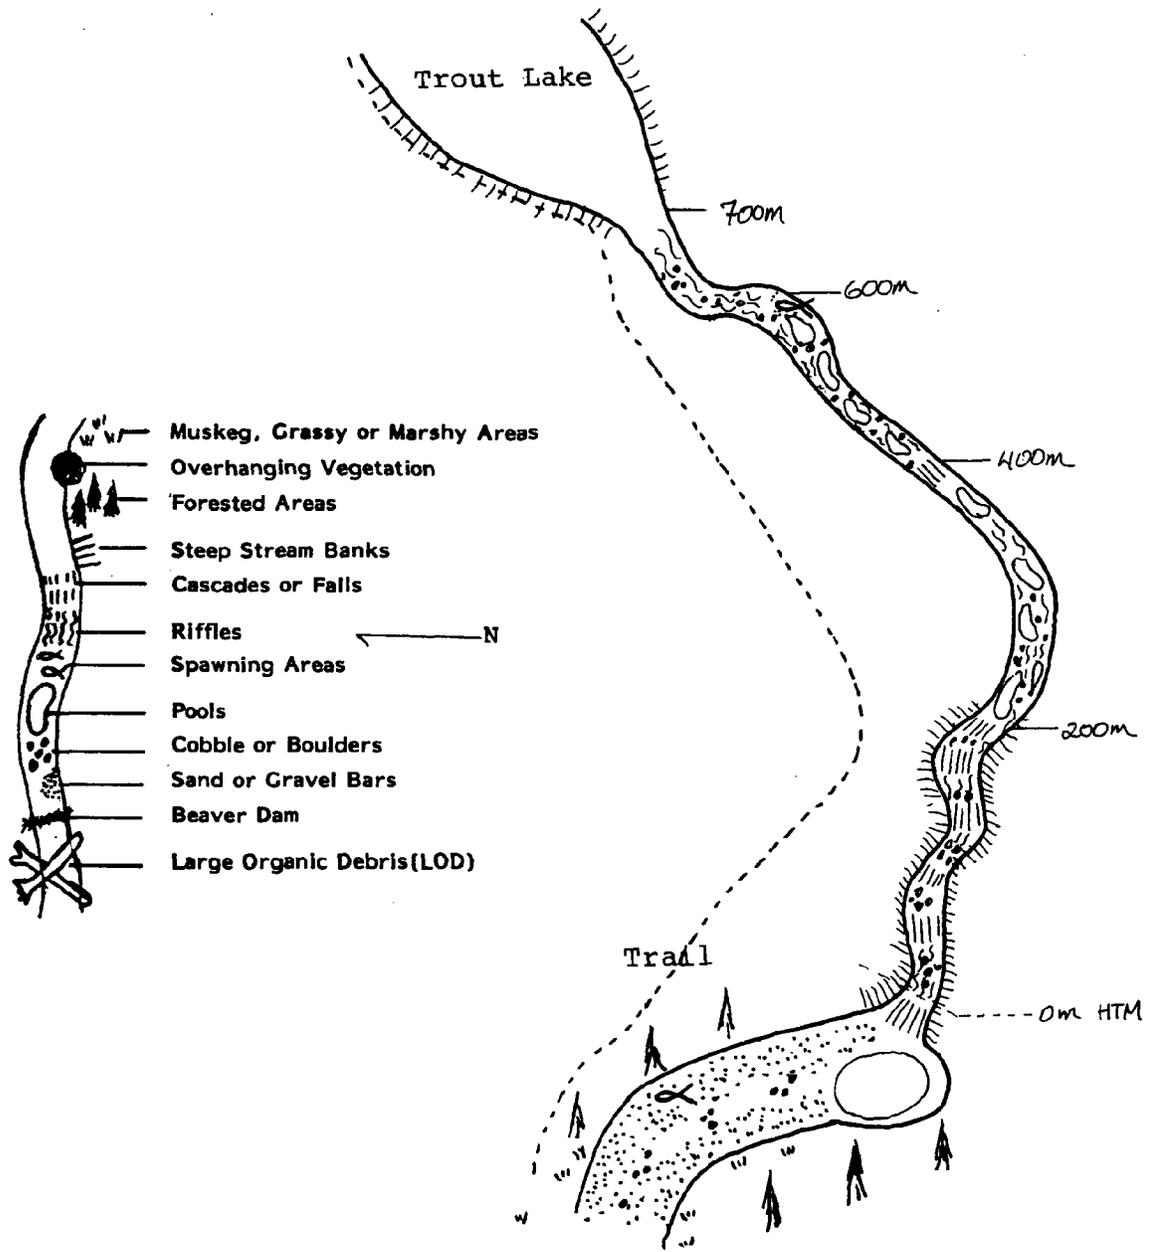

Recommended Escapement

Mainly salmonids traverse this creek on their way to Trout Lake tributary creeks, however, they will not be included on this form (only on the individual tributary forms). Only approximately 170 pink spawning pairs and 10 chum pairs are recommended for escapement in this creek.

Potential Production Summary

Due to the poor gravel quality intertidally, (1.2% egg-fry survival) probably only approximately 60 pinks return to Annette Island, however, in the upper reaches that chum utilize, 50 chum could return resulting from production in this creek (assuming a 10% egg-fry survival).

Figure 9. TAIN CREEK

Not In Scale

TAIN CREEK

Watershed No. 105-04
Stat. No. 101-28-010

Below 0m Intertidal area is mostly cobble and boulder, less than 5% available spawning area; large intertidal pool below 0m.

0m High Tide Mark (HTM), 1m Falls, not a barrier.

0-200m Cobble, boulder and bedrock substrate, high velocity flow.

200-400m Lower gradient, slower flow, Average Stream Depth (ASD) = .3m (shallower than lower section); riffle here; however, limited spawning area - gravels sparse and angular; at 400m, 25 ft. cascade chute (not a barrier).

400-600m Lower gradient, riffle area, mostly cobble/boulder bottom, 70m² spawning area at head of riffle at 600m (only spawning area seen so far).

600-700m Slow flow, low gradient, cobble/boulder bottom, Trout Lake at 700m.

Spawning Area: Limited
Above HTM 70m²

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Lower Trout Lake Creek		101-28-011	105-01	
Stream		Number	Geocode	
Flows S.W. into Lower Trout Lake- about 1.5 mi long.		Run-off from mountain slopes. /draining with granite outcroppings.		
Location		Origin	Watershed Type	
6/21/81	110m	Cascade barrier at 110m.	low flow	+2 ft (flashy)
Date Surveyed		Section Surveyed	Barriers	Stage
		Flow / Range	3 fps	7m
Ave. Gradient		Ave. Velocity/Range	Ave. Width/Range	Ave. Depth/Range
Gravel - dirt and rock, heavily vegetated with root wads and shrubs.		Relatively stable.	None	Flood Height
Streambank Composition		/ Stability	Tributaries	

Water Quality

10m Above Mouth	16 C	9 C	--	Clear	--	None	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO ₂	
--	--	--	--	--	--	--		
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall					

Spawning Area

Large gravels, cobble rubble.

Overall Stream Bottom Composition

Gravels rounded at mouth and become angular toward falls.

Gravel Compaction

Approximately 315m² available spawning area in fair qualities - some on a gravel bar - large gravel

Spawning Area Available Above High Tide Mark (HTM)

bar near mouth - not counted (probably not used).

Not Available

Intertidal Spawning Area

Rearing Area

One pond exists below the falls. Mainly a run and riffle.

Pool/Riffle Frequency (P:R Ratio)

1m

Ave. Pool Depth/Range

about 3m diameter

Ave. Pool Size/Range

Limited - some LOD and a side channel with a few undercut banks.

Available Cover

Scarce - none seen.

Aquatic Invertebrates/Available Food Source

Scarce - some brown mosses and periphyton near the mouth.

Aquatic Vegetation

A few shrubs (blueberry and huckleberry), mainly cedar and hemlock with a few alder, (fairly open understory).

Terrestrial Vegetation

70% from canopy (not riparian vegetation).

Shading

Limited - a little available inside channel - if fish use the creek to spawn, fry probably

Extent and Quality of Rearing Area

go directly to the lake.

Reported and Suspected Use of Stream by Fish and Fishermen

Probably sockeye, coho and trout only use the creek.

Use by Fish

Occasionally hunting (campsite near creek mouth).

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

This is a minor production creek (limited spawning area) with a little area available to sockeye, coho, and/or cutthroat. No improvements recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
None	Seen				

Survey(s) and Dates Conducted

E. Biggs, 6/21/81

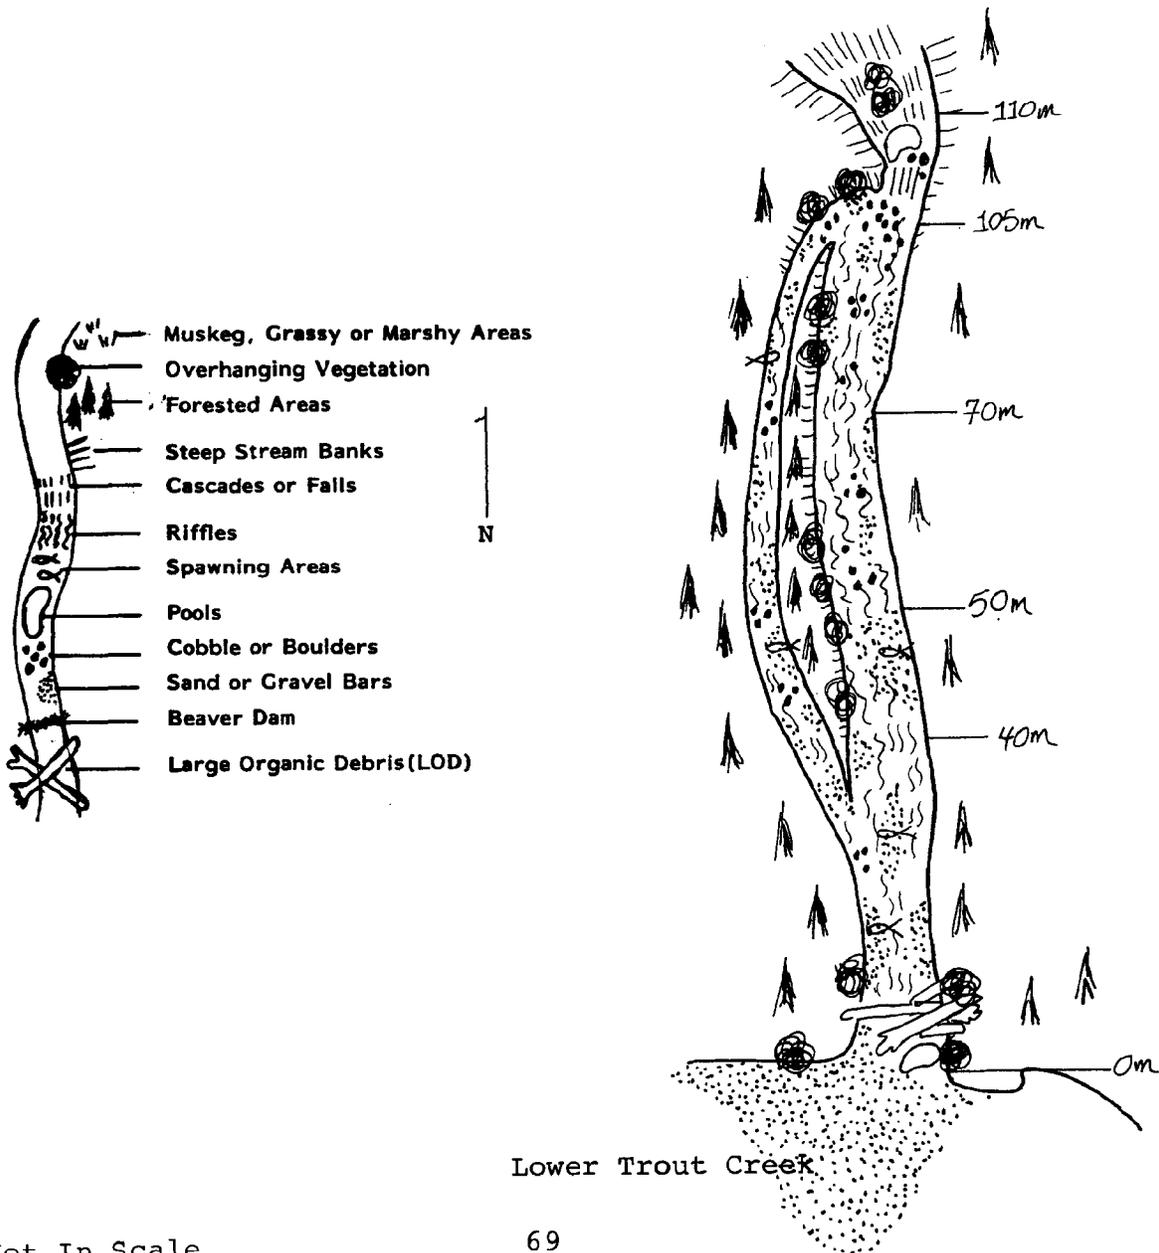

Recommended Escapement

Recommendations are made for sockeye and coho only. 47 sockeye spawning pairs and 27 coho spawning pairs could utilize this creek, however, due to the difference in timing, coho may disturb sockeye redds.

Potential Production Summary

Given the above escapements and a 10% egg-fry survival rate (good quality gravels present), it is estimated that 168 sockeye and 152 coho could return to Annette Island resulting from production in this creek.

Figure 10. LOWER TROUT LAKE CREEK

Not In Scale

LOWER TROUT LAKE CREEK

Watershed No. 105-01
Stat. No. 101-28-011

At Mouth - 0m Large gravel bar, extends into lake, gravels high quality (rounded), but with fines mixed in.

0-40m Average Stream Width (ASW) = 7m, 50% spawning gravels; side channel splits off to the west.

40-50m ASW = 5m, 90% spawning gravels.

50-70m ASW = 5m, gravels interspaced with boulders, 10-20% spawning gravels available during high flow.

70-105 ASW = 5m, gravels between boulders, 10% spawning gravels, side channel enters at 105m.

105-110m Bedrock and boulder cascade with a barrier falls/ cascade at 110m.

30-105m
(Side Channel)
ASW = 3m from 30-70m, with a low gradient and about 80% available spawning area during high flows - some rearing area, but its limited; above 70m, ASW = 1m, and spawning gravel decreases to 10% - interspaced in boulders.

Spawning Area:	0-40m	140m ²
	40-50m	45m
	50-70m	15m
	70-105m	18m
Side Channel		<u>97m</u>
Total	Approximately	320m ²

Spawning Area

Bedrock, boulders, and cobble interspaced with gravel spawning areas (see stream map description); there
Overall Stream Bottom Composition

would be more spawning area with less cobble and rubble intermixed. Minimal excellent gravels.

Gravel Compaction

Extensive area - probably critical to size of run in Trout Lake - 1972m² of excellent quality

Spawning Area Available Above High Tide Mark (HTM)

spawning gravels - with only a few "fines"

Not applicable.

Intertidal Spawning Area

Rearing Area

Many large pools throughout creek - high p:r	Main pools, .9m /up side pools .7m /to 1.5m	up 6m diameter /to 120m.
<u>Pool/Riffle Frequency (P:R Ratio)</u>	<u>Ave. Pool Depth/Range</u>	<u>Ave. Pool Size/Range</u>

Provided mainly by side pools with root wads and cobble bottoms.

Available Cover

Sparse - a few diptera, mayflies, caddisflies and stoneflies.

Aquatic Invertebrates/Available Food Source

Moss and algae relatively abundant.

Aquatic Vegetation

Riparian vegetation sparse - azaleas, skunk cabbage, currant and alder; timber is spruce, hemlock and cedar.

Terrestrial Vegetation

40% from canopy (forest) and topographic (steep banks).

Shading

Extensive rearing area in both upper lake (origin) and throughout creek. Many coho salmon are produced.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Sockeye, coho and cutthroat utilize creek.

Use by Fish

No known use by sports fishermen or otherwise.

Use by Fishermen

Wildlife Present

--

Comments and Recommendations

This is the major creek for spawning sockeye on Annette. It should be strictly protected and escapement

counts should be conducted yearly. No major habitat improvement recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/29/71	Sockeye	Fry	12		Young of the year = 0+
6/21/81	Coho	Fry	300		No sockeye!
9/19/81	Sockeye	Adult	19	3	Creek could hold alot more spawners.

Survey(s) and Dates Conducted

C. Huntington, 6/21/81 and USFWS, 9/29/71 and 9/26/72

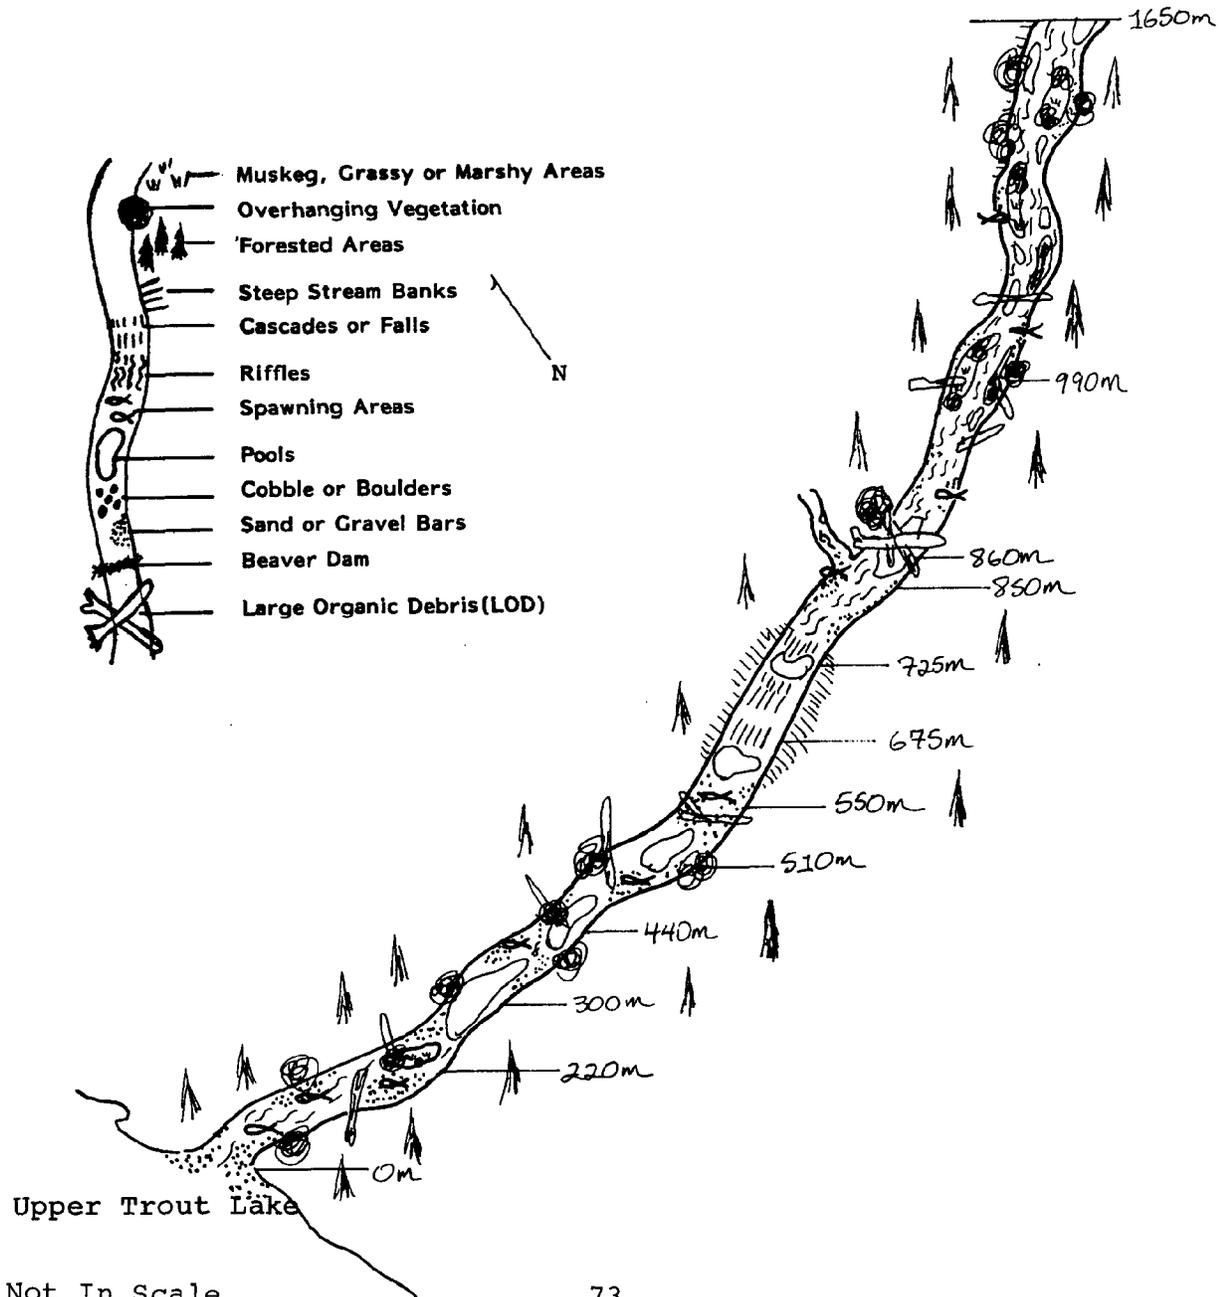

Recommended Escapement

Recommendations will be made for sockeye and coho only. 295 sockeye and 168 coho spawning pairs could utilize this creek successfully.

Potential Production Summary

With the excellent quality spawning gravels present and good water supply, a 20% egg-fry survival rate is assumed. Potential production given the above escapements would be 2100 sockeye and 1900 coho returning to Annette Island resulting from production in this creek.

Figure 11. NORTH UPPER TROUT LAKE CREEK - Section 1

Not In Scale

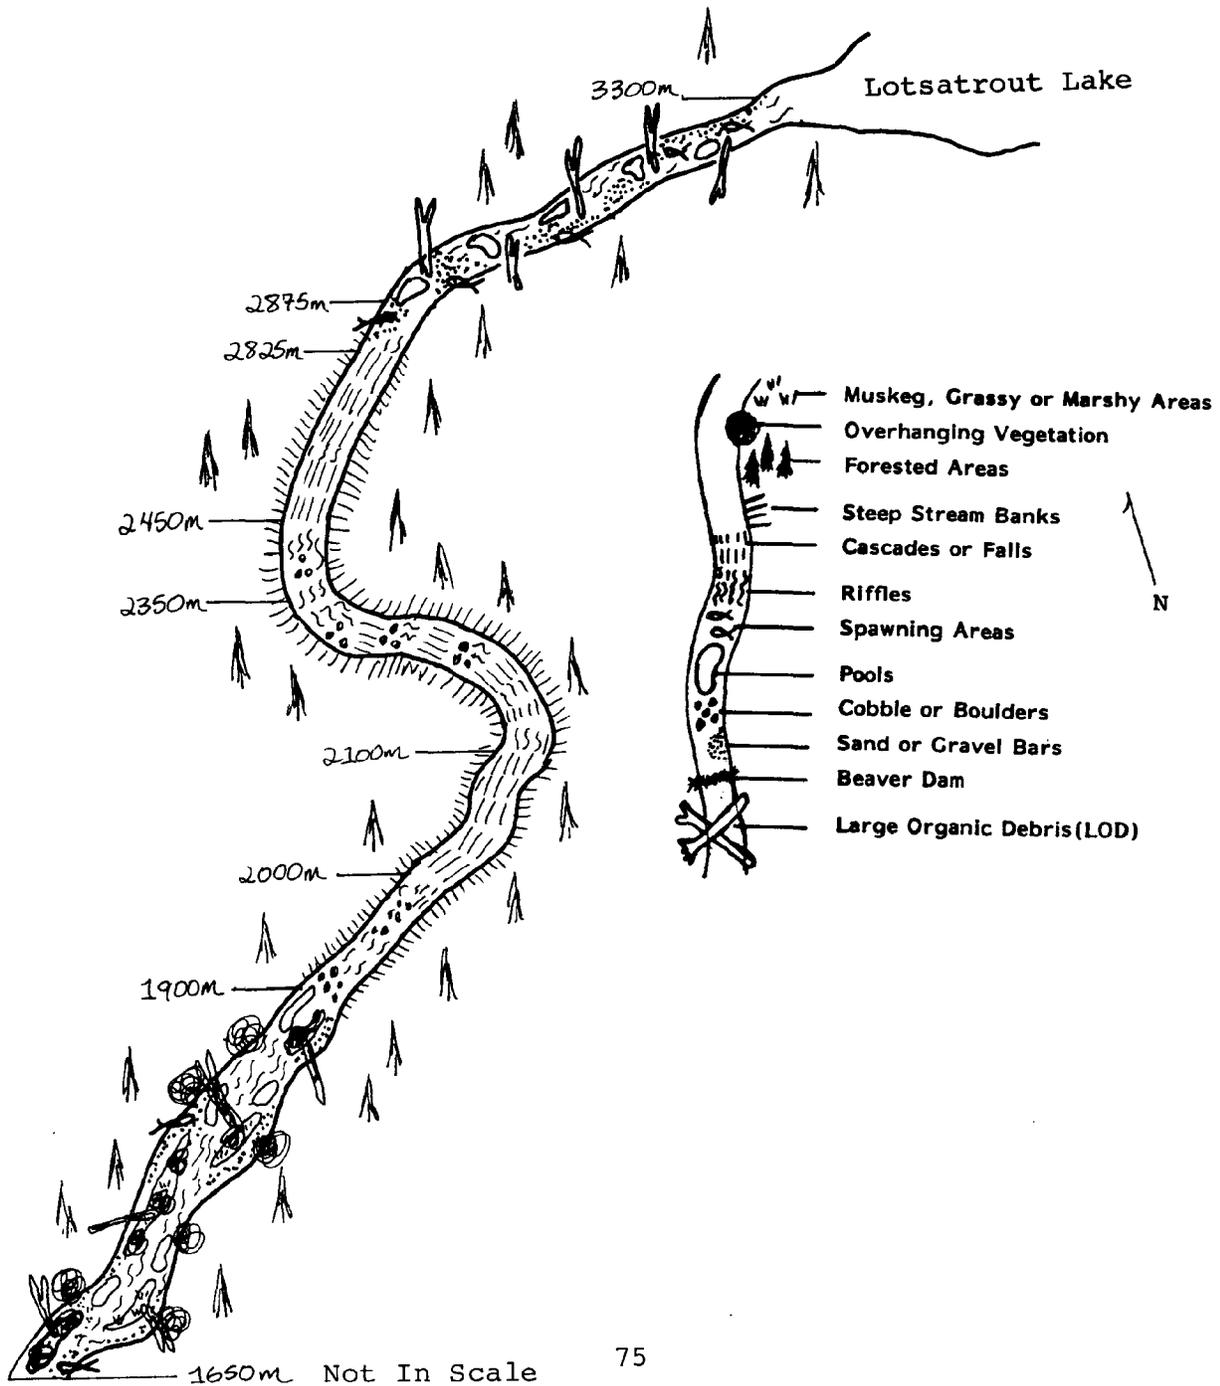

NORTH UPPER TROUT LAKE CREEK

Watershed No. 105-02
Stat. No. 101-28-012

- 0-550m Average Stream Width (ASW) = 12m, Average Stream Depth (ASD) = .45m, good spawning area, alot of rearing area available with large, deep side pools, much LOD and root wads, and large, deep pools in the channel. Island at 220m, 20 x 125m pool at 300m, 12 x 45m pool at 440m, 8 x 20m pool at 510m, and 110m long riffle at 550m.
- 550-725m Spawning area decreases; at 675m, there is a 2m high, stepped falls with a 30m diameter, 5m deep pool below it (not a barrier). At 725m, 2.5m stepped falls with a deep plunge pool.
- 0-725m Bottom composition: 5% pebble, 25% rubble, 30% cobble, 40% gravel.
- 725-1900m Bottom composition: 5% pebble, 10% gravel, 45% rubble, 35% cobble, 5% boulder. Good "off channel" rearing area with some LOD and root wads in side channels, ASW = 7m, ASD = .30m, gradient is less than 1% with slow water velocity; main channel is cobble and rubble with some boulders, with patchy spawning areas (< 50m²) in side pools ("tailout"). At 850m, a tributary enters that has some spawning and rearing area, but gravels are angular. LOD with pool at 860m and channel braiding with abundant side pools and good rearing habitat begins at 990m.

(CONTINUED,
SECOND SECTION)

Figure 12. NORTH UPPER TROUT LAKE CREEK - Section 2

NORTH UPPER TROUT LAKE CREEK (CONTINUED)

- 1650-1900m Braided channel and slow flow continues. At 1900m is end of good rearing habitat.
- 1900-2825m Bottom composition: 5% gravel, 20% cobble, 20% rubble, 25% boulder, 30% bedrock. Generally a steep gradient channel with little to no LOD, few large pools and swift velocity - little or no spawning or rearing area. ASW = 8m, ASD = .20m. At 2000m, relatively steep bedrock channel with passable cascades, which ends at 2100m. From 2350-2450m, gently sloping gradient bedrock channel with lots of moss and algae and at 2825m, the bedrock channel ends.
- 2825-3300m Bottom composition: 5% sand, 5% pebble, 75% gravel, 15% cobble. Low gradient (less than 1%) with moderate amount of LOD and pool formations; good spawning and rearing area with 2 old redds, at 2875m and coho fry observed.
- 3300m Lotsat trout Lake - rearing area for coho fry.
- Spawning Area: Total Available 1972m²
(760m² of which is in upper section)

ANNETTE ISLANDS STREAM SURVEY SUMMARY

South Upper Trout Lake Creek	101-28-013	105-03

--	--	--	--	Good				
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall					

Spawning Area

Alot of good gravels (90% of bottom in areas), but gravels become more and more angular above 800m - about

Overall Stream Bottom Composition

50% gravels, 30% rubble, 10% boulder, 10% sand.

Some - angular gravels

Gravel Compaction

Excellent quality spawning area, especially in lower half of creek; 5180m² available area total.

Spawning Area Available Above High Tide Mark (HTM)

Not applicable.

Intertidal Spawning Area

Rearing Area Pool substrates are mainly cobble and rubble. Pools and riffle interspaced throughout, 40-60% riffles (.2m deep)

Pool/Riffle Frequency (P:R Ratio)	.9m	.6-1.2m	.6m	to 1.5m
	Ave. Pool Depth/Range		Ave. Pool Size/Range	

Mainly provided by some LOD in braided channel and influencing the main channel - a little overhanging vegetation.

Available Cover

Moderate density - stonefly, mayfly and caddisfly larvae observed.

Aquatic Invertebrates/Available Food Source

--

Aquatic Vegetation

Some huckleberry, salmonberry, azalea, devil's club, terrestrial grasses - timbered areas are hemlock, cedar, shorepine and alder.

Terrestrial Vegetation

In general, 0-40%; 90% shading in a couple of areas (overhanging vegetation and LOD).

Shading

A fair amount - not as much as North Upper Trout Lake Creek, but still provides alot of coho fry.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Sockeye, coho and cutthroat use the creek.

Use by Fish

No use known by sportmen.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

This is a major spawning area for sockeye - underescapement is obvious - recommend strict fishing

regulations on lower creek to boost production. Coho fry growth may be limited in creek by low water

temperature.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/29/71	Sockeye	Adult	59	13	(mostly found in first large pool.)
	Cutthroat	Adult - 6 inch	1		
	Sockeye	Fingering	a few sited		
8/1/74	Cutthroat	4-6 inch	6		
	Coho	2-3 inch (fry)	21		
	Three spine sticklebacks	1.5-3 inch	12		
	Sculpin	Adult	a few spotted

1972	Sockeye	Adult	66		Escapement Peak Count
1974	Sockeye	Adult	125		Escapement Peak Count
6/21/81	Coho	Fry	20		More were seen, but uncounted.
9/19/81	None seen (sockeye adults expected).				

Survey(s) and Dates Conducted

J. Yuska, 6/21/81 and USFWS, 9/29/71 and 8/1/74

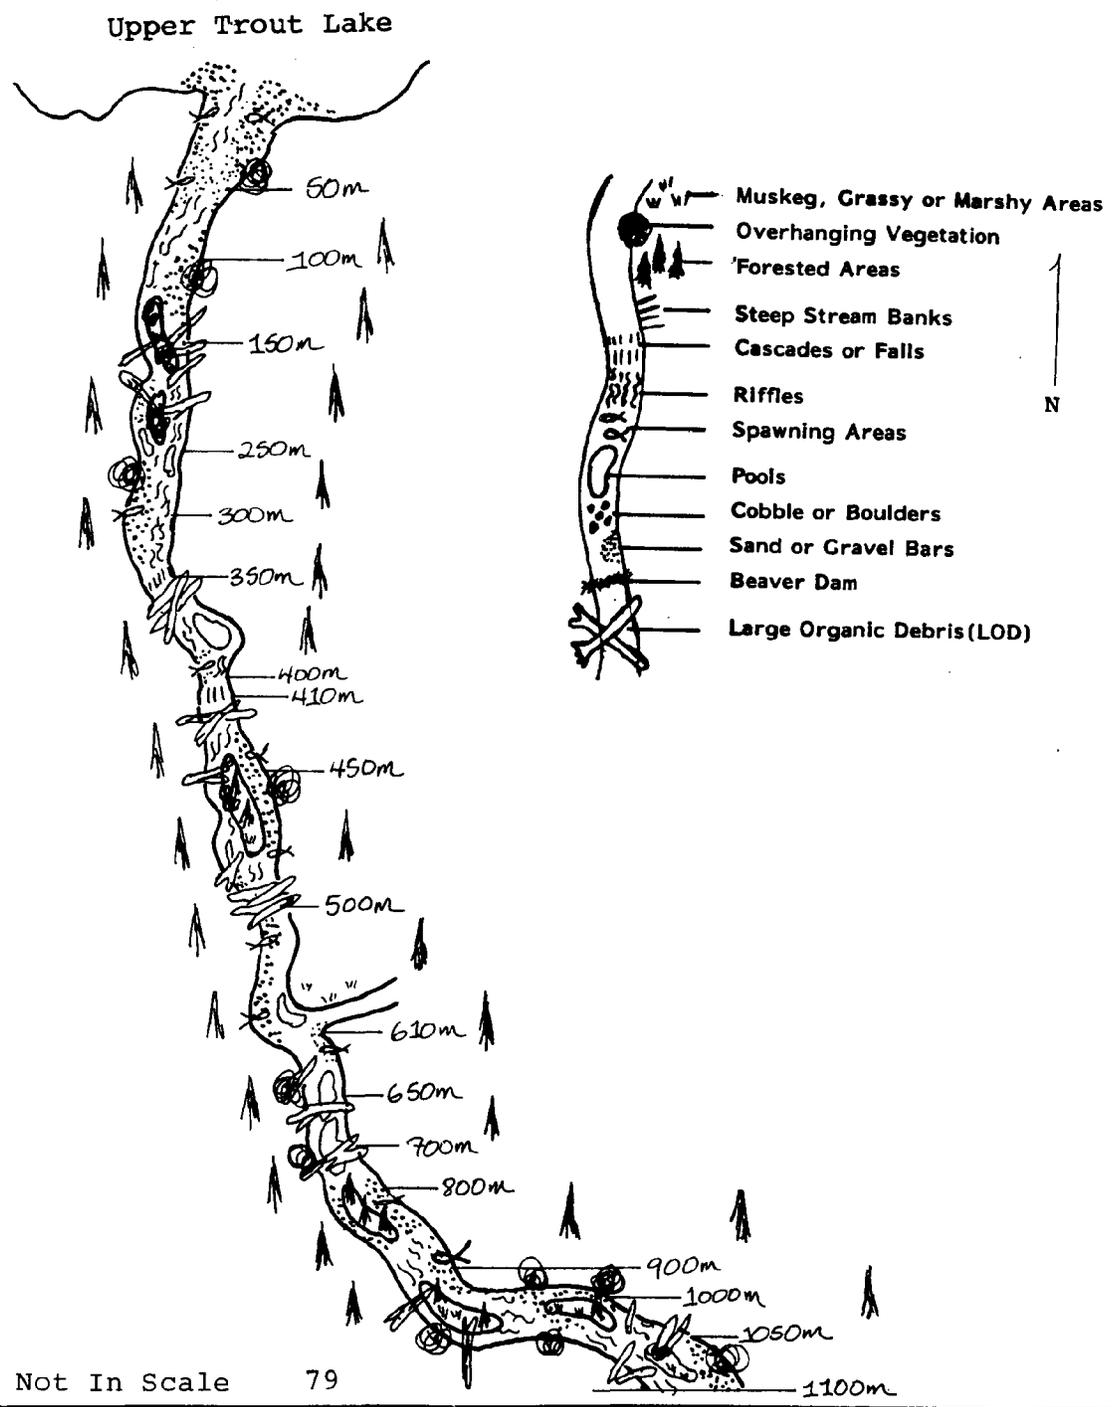

Recommended Escapement

There is an immense amount of spawning area available in this creek, 770 sockeye spawning pairs and 440 coho spawning pairs could utilize this creek.

Potential Production Summary

Because of the excellent quality gravels, but expected creek flashiness, a 10% egg-fry survival rate is assumed. Potential production with the above escapements, 2750 sockeye and 2480 coho could return to Annette Island

Figure 13. SOUTH UPPER TROUT LAKE CREEK - Section 1

SOUTH UPPER TROUT LAKE CREEK

Watershed No. 105-03
Stat. No. 101-28-013

0-50m Upper Trout Lake at 0m, Average Stream Width (ASW) = 10m, Average Stream Depth (ASD) = .45m, low gradient, low velocity, 90% spawning gravels.

50-150m ASW = 7m, ASD = .4m, at 100m stream is 3m wide, but including gravel bars at high flow, 9m wide; 60% usable gravels and gravel size increases.

150-250m Stream braids, alot of LOD in channel, gravels are larger, but clean, at 250m moderate amount of rearing habitat including root wads and backwater areas (still 60% gravels).

250-300m 60% spawning gravels; at 300m, channel is 3m wide with 5m gravel bars that are covered at high flows.

300-400m Still 60% gravels; at 350m, LOD forms falls .5m high.

400-450m Gravels increase in size, bottom is 30% gravels, 60% cobble, 10% boulder, at 410m is a LOD induced falls .5m high.

450-500m Braided channel begins at 450m with LOD piles and good rearing habitat; bottom is 90% gravels, 5% cobble, 5% boulder; a side channel has 100% gravel (100m² total spawning area in it).

500-800m ASW = 6m, with 50% spawning gravels over a low gradient, at 610m, a tributary with good off-channel rearing area enters - tributary ASW = 3m, ASD = .08m with 180m² of available spawning area during high flows. At 650m, good off-channel rearing areas, low gradient, with undercut banks and 40% shading from 0m.

800-900m Braiding occurs at 800m, ASW = 6m with 100% spawning gravel.

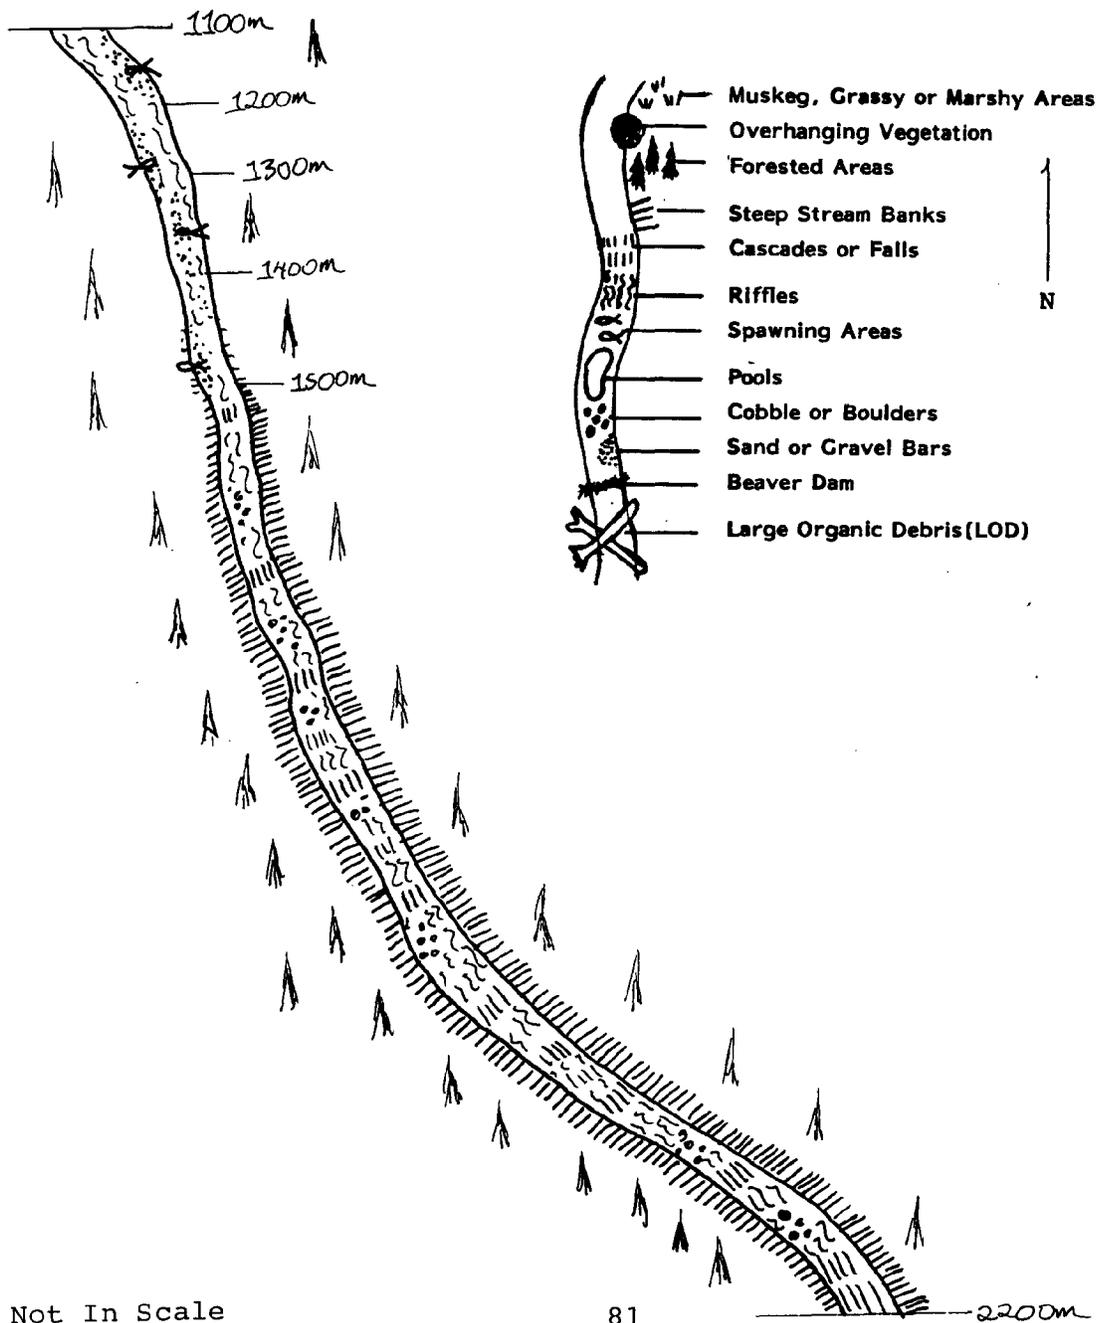

900-1000m ASW = 6m, with 50% spawning gravel.

1000-1100m ASW = 7m, 60% spawning gravel, at 1050m, a moderate amount of LOD and channel braiding ends at 1100m.

0-1100m Gravels are fairly rounded and clean.

(CONTINUED
SECOND SECTION)

Figure 14. SOUTH UPPER TROUT LAKE CREEK - Section 2

SOUTH UPPER TROUT LAKE CREEK (CONTINUED)

1100-1200m ASW = 5m, 60% gravels, no more channel braiding.
 1200-1300m ASW = 5m, 15% gravels.
 1300-1400m ASW = 4m, 10% gravels - size of gravel has increased.
 1400-1500m ASW = 3m, stream gradient has increased with the bottom having less than 5% gravels, being mostly large cobble, small boulders, and bedrock; very little rearing habitat here or above 1500m.
 1500-2200m Stream increases in gradient; no coho fry up this far; barrier falls at 2200m.

Spawning Area:

	0-50m	450m ²

Date Surveyed	Section Surveyed (9/21/71)		Barriers	
3.5%	15 cfs / up to 70 cfs/		3 fps / up to 3.5 fps/	
Ave. Gradient	Flow / Range		Ave. Velocity/Range	
Channel fairly open with rock (vegetated banks).	Stable		4m / up to 6m	
Streambank Composition	Stability		Tributaries	
Water Quality	9/21/71: 15.5 C		13.3C	
50m mark -	10.6C		12C	
stream flow station	Temp.-Air		Temp.-Water	
Sample Site	Ph		Ph	
17.1 ppm (9/21/71)	--		5.5 ppm due to CaCO ₃	
Total Alkalinity	Total Hardness		Dissolved Solids	
			Other/Overall	

Spawning Area

Cobble/boulder/bedrock channel.

Overall Stream Bottom Composition

Angular gravel.
Gravel Compaction

Less than 1% available spawning area above 4 ft falls at High Tide Mark (HTM), 10m² total, approximately.
Spawning Area Available Above High Tide Mark (HTM)

56m² at the most (14m wide, .2m deep average).

Intertidal Spawning Area

Rearing Area

Alot of deep pools.

Pool/Riffle Frequency (P:R Ratio)

--

Ave. Pool Depth/Range

--

Available Cover

Many aquatic dipterans.

Aquatic Invertebrates/Available Food Source

Scarce

Aquatic Vegetation

Mainly of stunted cedar and shorepine with a few alders - few shrubs.

Terrestrial Vegetation

15% or less due to canopy and riparian vegetation.

Shading

Poor and limited rearing habitat for coho; marginal to okay for steelhead.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Limited use (if any) by salmonids, pink and chum probably spawn intertidally.

Use by Fish

Not much subsistence or sport fishing.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

This creek has very limited spawning gravels and almost no available rearing (due to falls and cascades above). Lake is on a base of grandiorite, so lake tributaries probably have little good spawning gravels - not recommended for trout or salmon planting. A minor producer of salmon on Annette Island.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
1973	Rainbow	Fry	6100		Lake stocked with trout by USFWS
9/21/71	Pink	Adults (4.5 lbs. average)	53		
	Chum	Adults (10 lbs. average)	59		
6/6/81	None Seen	--	--	--	--

Survey(s) and Dates Conducted

C. Huntington, J. Yuska, E. Biggs, 6/6/81 and USFWS, 9/21/71

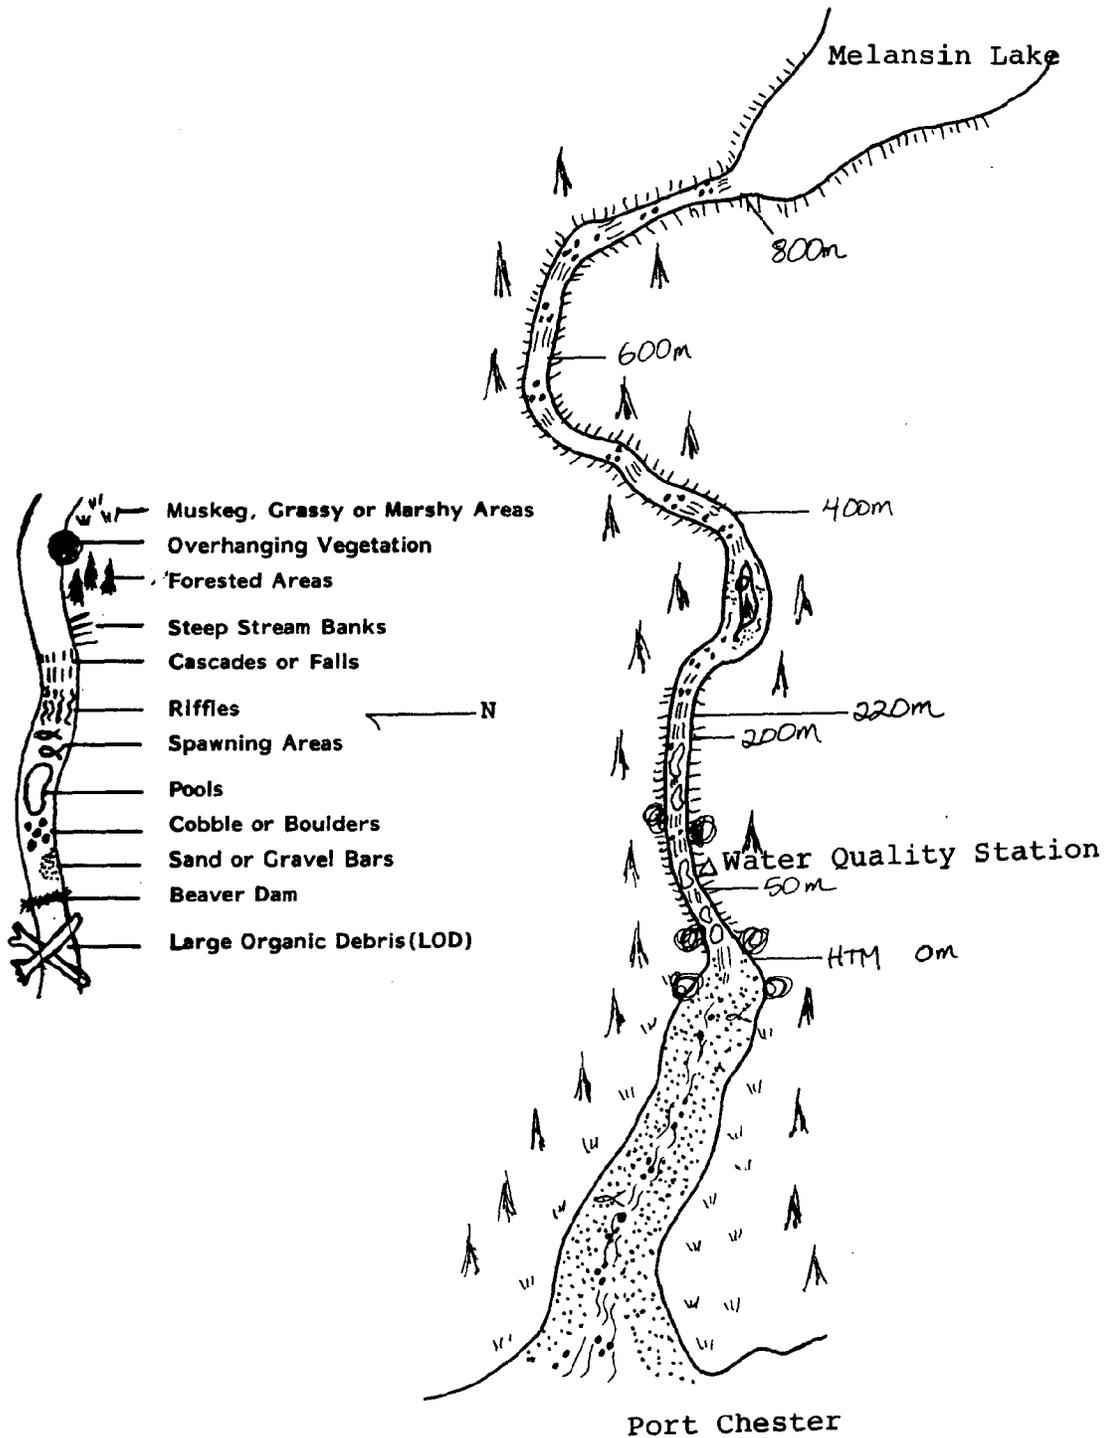

Recommended Escapement

This creek is of marginal value in production at present and only intertidal area is available and usable. At the most, 90 pink and 6 chum spawning pairs could utilize the area present.

Potential Production Summary

The gravel quality is poor, so a 1.2% egg-fry survival rate is assumed. Potentially, only 32 pinks and 4 chum would be expected to return as a result of production here.

Figure 15. MELANSIN CREEK

Not In Scale

MELANSIN CREEK

Watershed No. 104-01
Stat. No. 101-28-014

Intertidal Area to 0m

Gravels interspaced with cobble and boulders; less than 2% spawning area.

0m High Tide Mark (HTM) 2m high stepped falls.

0-50m Bottom mainly large cobble to small boulders with 5% spawning gravels. Streamflow gaging station at 50m.

50-220m Bedrock/boulder cascades, no spawning area. 25 ft barrier falls at 200m.

220-400m Low gradient area with one side channel; 5% spawning gravels.

400-800m Mostly bedrock and boulder; too difficult for fry passage; Melansin Lake at 800m.

Spawning Area: Limited

Approximately 50m² is available.

Shading

Limited because of lack of cover and shallow pool depth.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

None known.

Use by Fish

None known.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Creek probably not utilized by salmonids - no available gravels - no fish seen or expected.

Survey(s) and Dates Conducted: E. Biggs, C. Huntington, 6/21/81

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Davis Creek		101-28-016		102-02	
Stream		Number		Geocode	
Flows N into Pt. Chester, 1.5 mi long		Small lake and muskeg run-off.		Muskeg marsh and forested foothills.	
Location		Origin		Watershed Type	
1500m above High Tide		Muskeg area at 1500m		Low flow	
6/4/81		Barriers		Stage	
Date Surveyed		Section Surveyed		Flood Height	
3%		2 cfs		3.6m	
Ave. Gradient		Flow / Range		3-4.5m	
Moderately steep banks to the muskeg of bedrock and fragmented rock.		rapid over 1 fps		.45m	
Streambank Composition		Stabilized by roots and LOD.		Two and stream splits at 1500m.	
		/ Stability		Tributaries	
Water Quality		9/7/71: 12.3C		11.7C	
Above culvert.		10.0C		10.5C	
Sample Site		Temp.-Air		Temp.-Water	
17.1 ppm (9/7/71)		48.2 ppm (9/7/71)		--	
Total Alkalinity		Total Hardness		Dissolved Solids	
				Other/Overall	

Spawning Area

Gravels interspaced in boulders with lots of bedrock in the channel (some bottom material is angular);

Overall Stream Bottom Composition

there are a couple of sand bars, but fines are minimal.

No fines or compaction, clean excellent quality gravels.

Gravel Compaction

Definite redds found - suitable gravels are present to the 1400m mark. Approximately 700m² of total

Spawning Area Available Above High Tide Mark (HTM)

area exists.

None (cobble/boulder substrate mixed with some fines).

Intertidal Spawning Area

Rearing Area

Mainly riffles in creek - a few pools.

Pool/Riffle Frequency (P:R Ratio)

Shallow/ one to 1m deep

Ave. Pool Depth/Range

Small/ One to 7.5m diameter

Ave. Pool Size/Range

Some available, with a few undercut banks and slack water areas, some LOD in the channel and root tangles.

Available Cover

Sparse - a few trichoptera, ephemeroptera and diptera (sparse probably because of low Ph).

Aquatic Invertebrates/Available Food Source

Some filamentous algae growth, alot of mosses present.

Aquatic Vegetation

Thick and tight riparian vegetation to muskeg areas made up mainly of skunk cabbage, salal, salmonberry and alder; timber is spruce, cedar and hemlock.

Terrestrial Vegetation

Intense - 90% mainly due to riparian vegetation.

Shading

There is a moderate amount of coho rearing area, but low Ph and low abundance of insects are probably

Extent and Quality of Rearing Area

limiting factors to production. Much rearing area is physically good for steelhead.

Reported and Suspected Use of Stream by Fish and Fishermen

Chum, coho and pinks use the creek.

Use by Fish

Subsistence fishing and egg take for hatchery (Fall, 1980).

Use by Fishermen

Wildlife Present

--

Comments and Recommendations

Many pink and chum use this creek along with coho; so subsistence fishing should be regulated and

controlled; a gravel pile under the culvert may help fish get through it (there is a 3 ft drop at HTM). Water quality and food abundance may be limiting factors to production.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/7/71	Coho	Fry (55mm)	30	--	
9/1/71	Pink	Adult	30	--	
9/15/71	Pink	Adult	--	30	These were found speared - not natural mortality.
9/20/71	Pink	Adult	--	32	Found 1/2 mile up the creek.
1972	Pink	Adult	270	--	USFWS Escapement Estimate
1973	Pink	Adult	100	--	USFWS Escapement Estimate
1974	Pink	Adult	712	--	USFWS Escapement Estimate
1975	Pink	Adult	750	--	USFWS Escapement Estimate
1076	Pink	Adult	1165	--	USFWS Escapement Estimate
9/1/81	Pink	Adult	60	--	Aerial count - fish ball seen at creek mouth.

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, J. Yuska, 6/4/81, and USFWS, 9/7/71

Recommended Escapement

Recommended escapements according to available spawning area are 600 pinks, 40 chum and 10 coho (according to rearing area) spawning pairs.

Potential Production Summary

With good-excellent quality gravels, a 10% egg-fry survival rate is assumed. Give the above escapements, production potential is 1780 pinks, 200 chum and 56 coho returning to Annette Island.

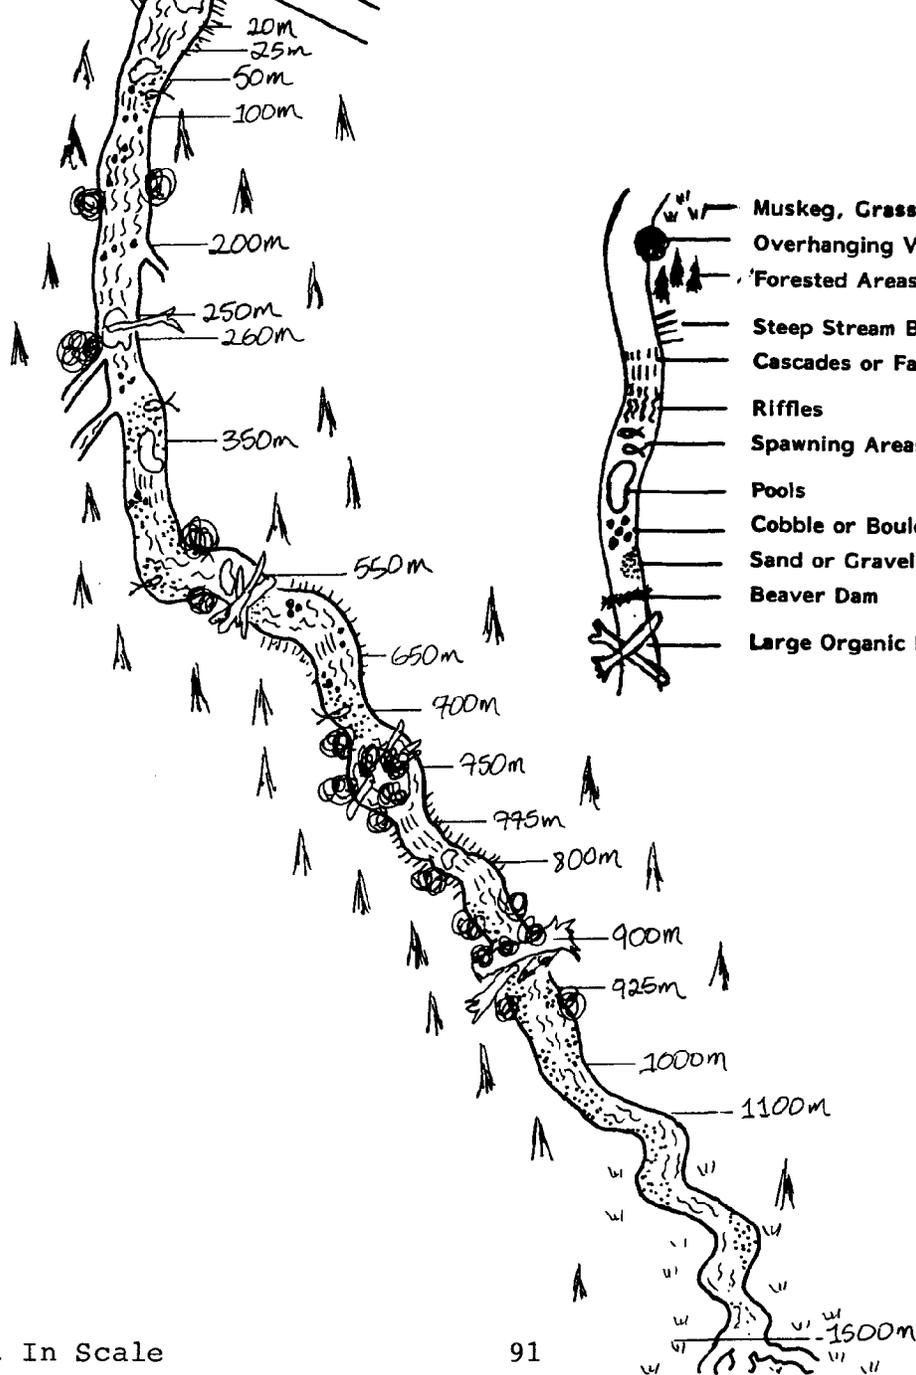

Port Chester

Figure 16. DAVIS CREEK

Vallner Point Road

HTM

0m

N

Not In Scale

DAVIS CREEK

Watershed No. 102-02
Stat. No. 101-28-016

Intertidal Area (Below Road Culvert)

Mainly cobble and boulder and gravels with fine sediment mixed in.

- 0m Upstream side of road culvert, High Tide Mark (HTM).
- 0-100m 120m² spawning area just above the culvert, then an .08m deep spawning riffle at 25m. At 50m is a pool .8m deep with high, overhanging stream banks 6-7m long. At 100m is a long glide over bedrock.
- 100-200m 70% spawning area with a decrease in gradient and 50% overhead canopy shading, gravel are good size, but angular and a first order tributary enters at 200m.
- 200-350m Fewer gravels, but good rearing area; at 250m is a large pool and two first order tributaries enter, one at 260m and one at 300m. At 350m, gradient increases again and 20% good spawning gravels occur at the "tailout" of a plunge pool.
- 350-550m Most gravels too large for spawning; alot of LOD and debris jam potential.
- 650m Very little spawning area available.
- 700m 25m section with spawning gravels. Average Stream Width (ASW) = 1-1.5m.
- 750m Island
- 775m Scores of steep cascades with large angular boulders.
- 800m Series of falls (steep), blockage to pinks with a 2 cfs flow.
- 900m 1 diameter live cedar log across creek.
- 925m Gradient drops and 25% available spawning area occurs; moss and filamentous algae are present.
- 1000m Gradient low, gravels are small with alot of fines; ASW = 1m, Average Stream Depth (ASD) = .35m, alot of aquatic moss and algae occur.
- 1100m Above here, channel narrows considerably with a U-shaped cross section and fine sediment bottom (no spawning area).
- 1500m Stream breaks into muskeg.

Spawning Area:	0-100m	225m ²	
	100-200m	100m	
	350m	20m	
	350-1400	<u>350m</u>	- approximately

Date Surveyed		Section Surveyed		Barriers	
Low - 3%		--		1 fps / to slow	
Ave. Gradient		Flow / Range		Ave. Velocity/Range	
Soils stabilized by roots and heavy vegetation - LOD may add organic load to creek.		Stabilized		Stabilized	
Streambank Composition		/ Stability		None	
Water Quality		6/9/72: 15.0C		13.3C	
Above second culvert.		12.2C		14.0C	
Sample Site		Temp.-Air		Temp.-Water	
Trace (6/9/72)		12.0ppm (6/9/72)		9.1ppm-CaCO ₃ (6/9/72)	
Total Alkalinity		Total Hardness		Dissolved Solids	
				Other/Overall	

Spawning Area

Mud and silt in gravel and rubble - some sand; much of bottom is mucky with high amount of organic matter.
Overall Stream Bottom Composition

Siltation of gravels has occurred.
 Gravel Compaction

None- too many fines in gravel - former report (in 1972) states that 80% good spawning was available.
Spawning Area Available Above High Tide Mark (HIM)

None- creek flows under lumber yard - through two culverts, culvert under Vallner Point Road could be a barrier (two foot drop).
Intertidal Spawning Area

Rearing Area

Pools in 20% of stream, riffles in 50%.	.15m	--	1.2 x 3m	--
<u>Pool/Riffle Frequency (P:R Ratio)</u>	<u>Ave. Pool Depth/Range</u>		<u>Ave. Pool Size/Range</u>	

Undercut banks, some LOD and Skater's Lake.

Available Cover

Sparse - a few Odonata and ephemeroptera.

Aquatic Invertebrates/Available Food Source

Scarce - primarily composed of microforms.

Aquatic Vegetation

Heavy shrubs and alder and near lake is tall grasses and shrubs.

Terrestrial Vegetation

90-100% to trailers (due to heavy riparian vegetation); 30% past trailer court to lake.

Shading

Rearing area is okay - moderate amount of area available, as long as pollution does not interfere with

Extent and Quality of Rearing Area

the physiology.

Reported and Suspected Use of Stream by Fish and Fishermen

Creek not utilized by salmonids any more (may have been coho at one time). Pinks and chum used to use creek

Use by Fish

No fishing.

Use by Fishermen

Wildlife Present

--

Comments and Recommendations

Pollution problems and siltation seems to have destroyed the production potential of the creek. An updated, full water quality test (BOD, COD, pH, coliform counts, etc) should be conducted. Siltation problem may be hard to deal with because of road run-off and sewage seepage; it may help to reduce flow impedences and make second culvert passable.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
1971	Pink & Chum	Adult		Not counted	Residents reported these fish in the creek this year.
1972	Pink	Adult	100		USFWS Escapement Estimate
1973	Pink	Adult	100		USFWS Escapement Estimate

Survey(s) and Dates Conducted

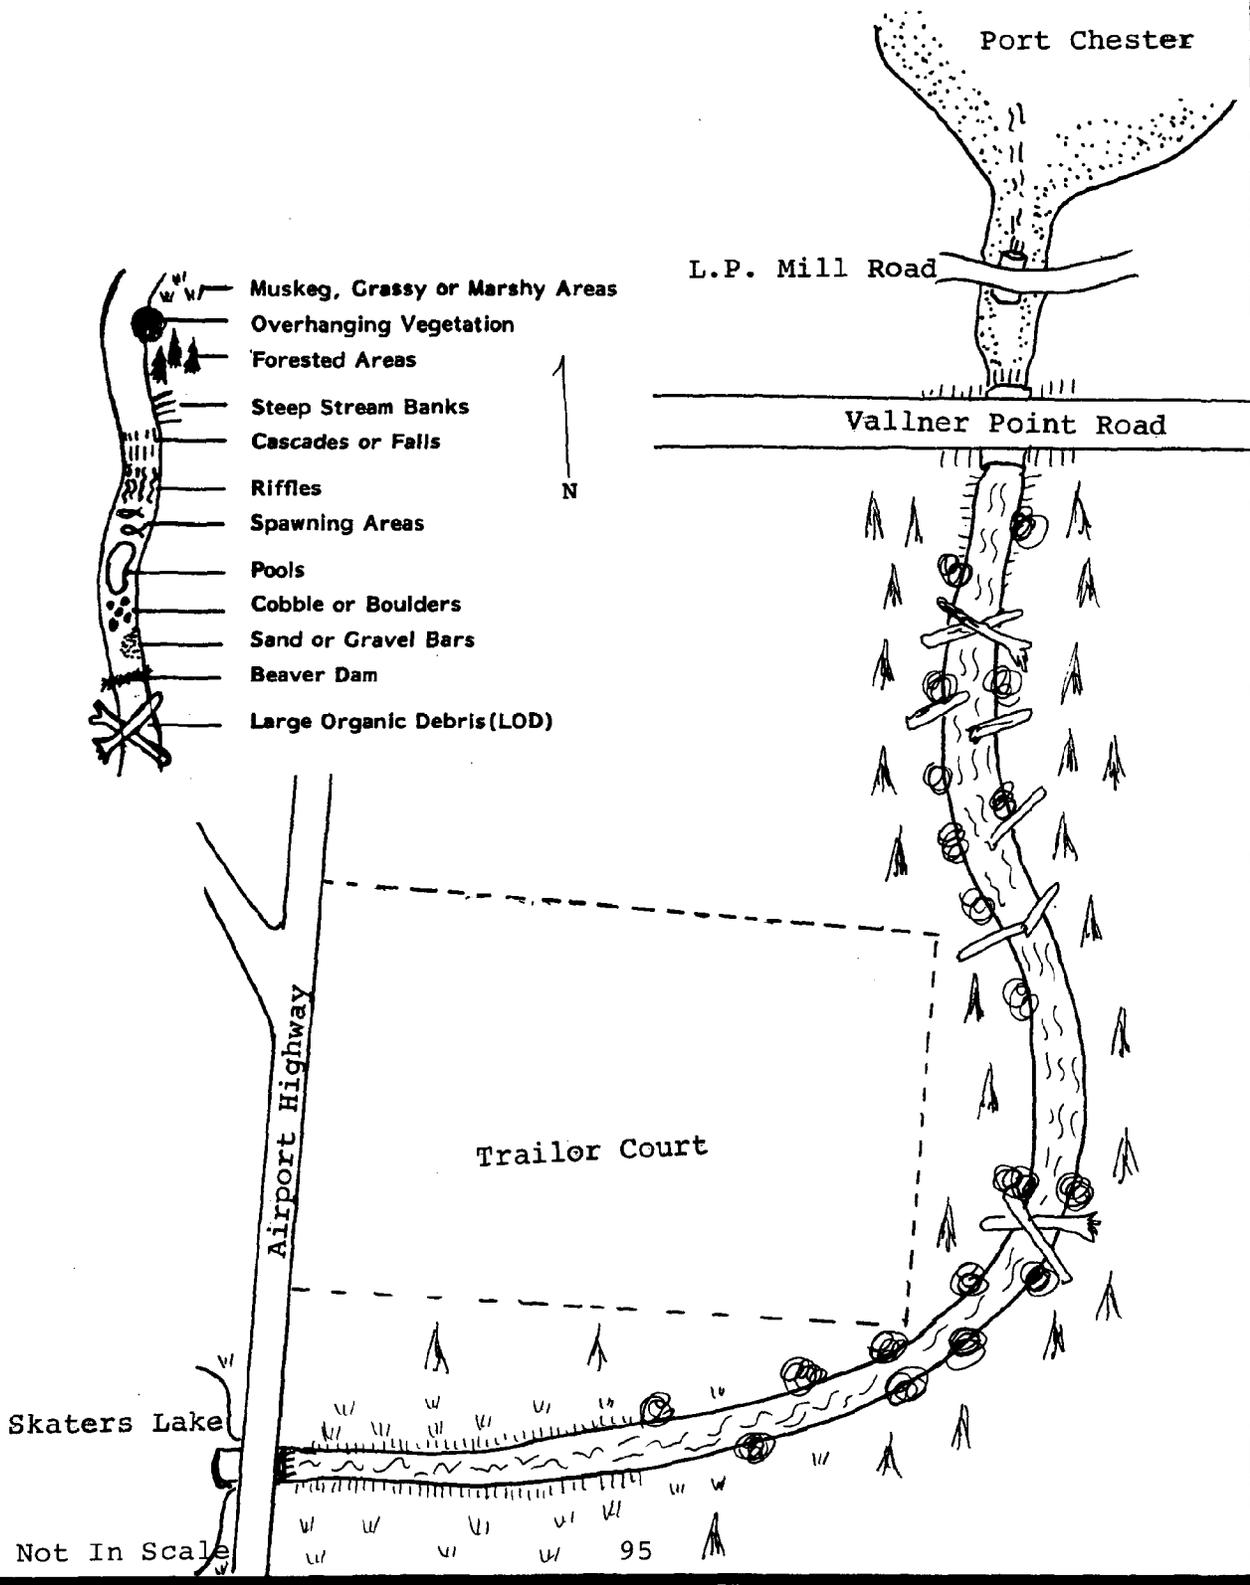

E. Biggs, C. Huntington, 6/21/81 and USFWS, 6/9/72

Recommended Escapement

No recommended escapements should be made until this creek is rehabilitated.

Potential Production Summary

Figure 17. SAWMILL CREEK

Skaters Lake

17.1ppm (9/7/71)	34.2ppm (9/7/71)	28.44ppm (9/7/71)	Okay - siltation is a problem in areas.				
<u>Total Alkalinity</u>	<u>Total Hardness</u>	<u>Dissolved Solids</u>	<u>Other/Overall</u>				

Spawning Area

Mainly small gravels, pebbles, sand and some silt and organic matter - larger rock occurs above second
Overall Stream Bottom Composition
 culvert. Some with fines mixed in gravels.
 Gravel Compaction

Redds found - 2.5% spawning area overall in creek of fair quality spawning gravels; 45m² total area
Spawning Area Available Above High Tide Mark (HTM)
 available.

None - creek flows over sand/rubble beach.

Intertidal Spawning Area

Rearing Area

Pools are numerous throughout creek, (some organic debris in pools), 6:1 ratio. .25m / to .6m 2.5 x 3.5m / --
Pool/Rifle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range
 Abundant cover available under overhanging vegetation, intense shading, alot of root wads, undercut banks and heavy amount of LOD (with pool formations).

Available Cover

Sparse - some diptera and trichoptera - but more here than in other muskeg creeks on Island.

Aquatic Invertebrates/Available Food Source

Sparse.

Aquatic Vegetation

Extremely developed stream margin of salmonberry, currant, skunk cabbage, ferns and root tangles under cedar, hemlock, spruce and alder.

Terrestrial Vegetation

90% intense shading up to 100% in areas - due to heavy riparian vegetation and canopy.

Shading

Excellent coho rearing areas throughout creek in undercut banks, LOD, deep pools and backwater areas,

Extent and Quality of Rearing Area

under root wads - many fry observed.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, coho, and cutthroat utilize creek.

Use by Fish

Reported heavy subsistence fishing in the fall (but no known sport fishing).

Use by Fishermen

Wildlife Present

Beaver, mink, and land otter observed in previous years.

Comments and Recommendations

This creek, because of the limited spawning area, but extensive rearing area, is significant in production of coho versus pinks and chum (although they utilize the creek). Manage and protect as an important nursery area and especially restrict fishing during escapement of coho (looks like there may be underescapement problem). No habitat improvements are recommended.

6/6/81	Coho	Fry	200	--	More seen, but uncounted.
	Cutthroat	Fry (0+ age)	About 50	---	
9/1/81	Pinks (mixed)	Adults	100	--	Fished balled up at mouth - aerial survey.

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, J. Yuska, 6/6/81 and USFWS, 9/7/81

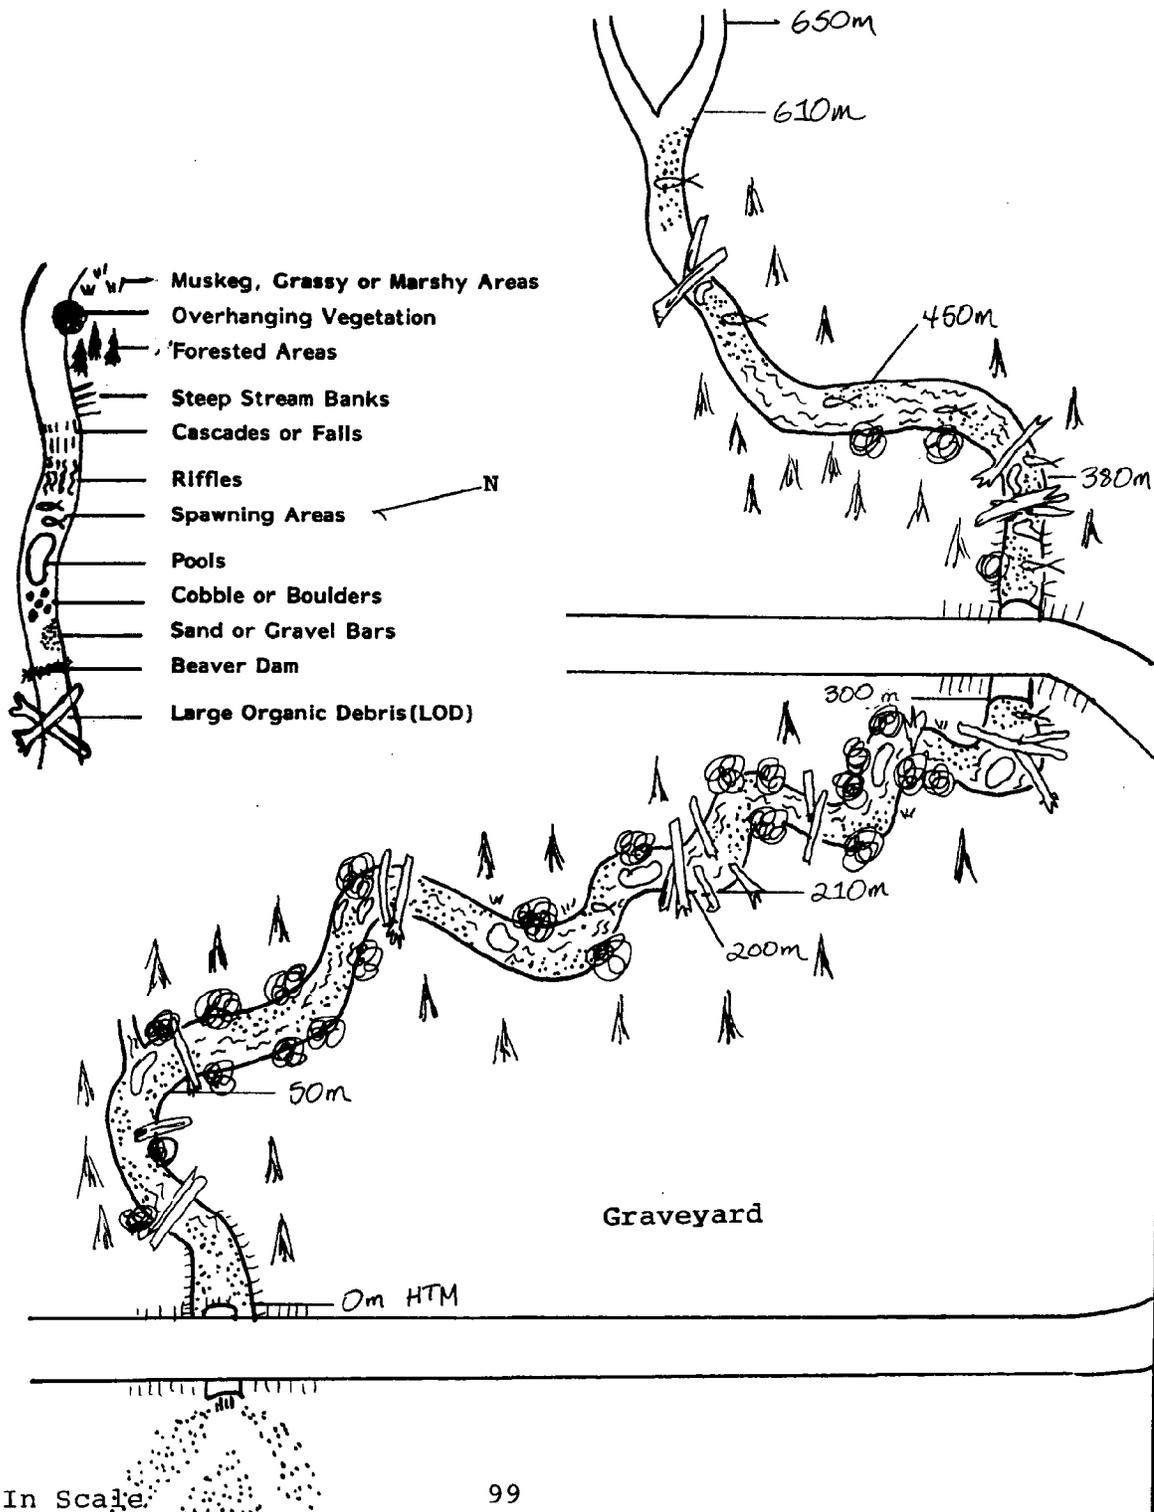

Recommended Escapement

Limited spawning area is available, only 75 pinks, 5 chum and 4 coho spawning pairs are needed to utilize all the available area.

Potential Production Summary

Gravel quality is fair, a 10% egg-fry survival rate is assumed. 223 pinks, 25 chum and 23 coho could return to Annette Island assuming the above escapement rates occurred.

Figure 18. GRAVEYARD CREEK

Not In Scale

GRAVEYARD CREEK

Watershed No. 101-01
Stat. No. 101-28-018

Intertidal Creek flows over sand and pebble beach, no spawning area.

0m High Tide Mark (HTM) at passable road culvert.

0-50m Average Stream Width (ASW) = 2m with alot of sand bars and LOD; spring seepage at 50m.

50-200m Alot of deep, undercut banks with excellent cover, steep banks and choked with woody debris; excellent rearing habitat and many coho fry observed.

200-300m LOD, undercut banks, and cover continues, and size of gravel increases. At 210m, spring seepage occurs and at 300m, 5% gravels occur (although they are angular); second road culvert here.

300-380m ASW = 1.75m, Average Stream Depth (ASD) = .15m, bottom is mainly mossy cobble and small boulders with 5% spawning area, many pools occur; amount of overhanging shrubs decrease, canopy mainly of trees.

380-450m Crumbly rock banks that are a good source of gravel and fine sand; more mature trees occur here.

450-650m Same as above, still only 5% gravels. Stream forks at 610m, north fork is 1m wide, .1m deep with fine gravels too small for spawning and south fork is also poor spawning area; mainly muskeg "land bridges" (creek flows under vegetation). Survey ended at 650m - creek flows into muskeg.

Spawning Area: Limited

Approximately 45m² available spawning area.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Far North Smuggler Creek		101-28-020	101-02
Stream		Number	Geocode
Flows S into Smuggler Cove, about 5 mi. long.		Muskeg and small lake drainings.	Muskeg and timbered flats.
Location	450m above High Tide	Origin Possibly log jam at HTM and muskeg areas at 250m.	Watershed Type
6/15/81	Mark (HTM)	Moderate Flow	--
Date Surveyed Section Surveyed		Barriers	Flood Height
Low - about 1-3%	.35cfs / --	Slow - .5 fps/ --	1.5m / --
Ave. Gradient	Flow / Range	Ave. Velocity/Range	Ave. Width/Range
Banks high in places - muskeg and rocks with root tangles.	Stable - extensive LOD influence on channel.	None	Ave. Depth/Range
Streambank Composition	/ Stability	Tributaries	

Water Quality

10m above HTM	10.6C	10.0C	--	Clear / None	Dark Brown	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO ₂
--	--	--	--	Strong muskeg influence.			
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

10% silt, 15% sand, 30% pebble, 40% gravels (less than or equal to 2cm in diameter).
 Overall Stream Bottom Composition

Moderate - most gravel too fine for salmon.
 Gravel Compaction

3% available spawning area - about 20m² area, but gravels are marginal, too many fines mixed in.
 Spawning Area Available Above High Tide Mark (HTM)

Limited - less than 10m² area available.
 Intertidal Spawning Area

Rearing Area

p:r = 4:1

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
Lots of LOD, slash, undercuts and root wads - extensive cover.		
Available Cover		
Sparse		
Aquatic Invertebrates/Available Food Source		
Sparse.		
Aquatic Vegetation		
Stunted trees and muskeg vegetation.		
Terrestrial Vegetation		
50% banks and riparian vegetation.		
Shading		
Good coho rearing area - limited by small size of creek.		
Extent and Quality of Rearing Area		

Reported and Suspected Use of Stream by Fish and Fishermen

Probably only pinks and trout could use gravel.

Use by Fish

No fishing or hunting activity - known.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Creek of minor importance in production (limited) - most gravels are too fine for use by salmon. An old shack was found at 25m and a trash collector dam at 100m; log jam at mouth may act as a barrier during low flows.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/15/71	Unidentified Salmonid	Fry	1		At 200m above creek mouth.

Survey(s) and Dates Conducted

C. Huntington, 6/15/81

Recommended Escapement

Due to the small gravel size, only pinks would be expected to utilize this creek and due to the limited spawning area, the escapement recommendation is only 50 pink spawning pairs.

Potential Production Summary

Due to the marginal gravel quality, a 1.2% egg-fry survival rate is assumed with a production potential of 18 pinks returning to Annette Island.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

North Smuggler Creek		101-28-021	101-03
Stream Flows SW into Suggler Cove, about 1 mi long.		Number Drains small lake NW of Yellow Hill Lake and muskeg run-off.	Geocode Muskeg and timbered flats.
Location 1400m above High Tide		Origin Possibly by beach	Watershed Type
Date Surveyed 6/15/81	Mark (HTM) 1400m above High Tide	log jam. Barriers	Low to moderate. Stage
Section Surveyed 1.5% upper end, 3% upper reach		Flow 1.25 cfs / --	Ave. Velocity/Range 1 fps / --
Ave. Gradient Fragmented rock, root tangles and some organic matter. / Fairly stable, but creek channel moves a bit		Ave. Width/Range 1.5m / --	Ave. Depth/Range .15m / --
Streambank Composition / Stability		Tributaries at high flow - moderate LOD influence.	Flood Height --

Water Quality

--	10.6C	12.0C	--	Clear/ None	Brown	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO₂
--	--	--	--	Muskeg water	--	--	--
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

5% silt, 15% sand, 10% pebble, 35% gravel, 15% rubble, 5% boulder and a trace amount of bedrock.

Overall Stream Bottom Composition

Not bad - some fines.

Gravel Compaction

Some gravels are packed in behind LOD - 300m² total area available; 275m² occurs in first 600m, 25m²

Spawning Area Available Above High Tide Mark (HTM)
occurs in 1000-1400m of creek.

Limited to approximately 10m².

Intertidal Spawning Area

Rearing Area Mostly riffles at lower end and more

p:r = 1:1 - riffles occur at higher flow.

Pool/Riffle Frequency (P:R Ratio)	--	--	--	--
	Ave. Pool Depth/Range	Ave. Pool Size/Range	--	--

Moderate LOD influence creating some pools and overhanging root wads.

Available Cover

Sparse - some ephemeroptera, trichoptera, and diptera.

Aquatic Invertebrates/Available Food Source

Heavy filamentous algae in small pools.

Aquatic Vegetation

Alot of currant, salmonberry and ferns under a hemlock, cedar and spruce canopy.

Terrestrial Vegetation

95% due to a heavy riparian understory, canopy and some topography (banks).

Shading

A fair amount is available in the summer (for coho); however, in the winter, most of creek is probably

Extent and Quality of Rearing Area

riffles, runs and swift water.

Reported and Suspected Use of Stream by Fish and Fishermen

Coho, pink, chums and cutthroat trout probably utilize creek.

Use by Fish

No fishing or hunting known.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Beach log jam at mouth is passable at high tide and high flow, otherwise, it is a barrier. This is a pretty good coho creek, but does not produce large numbers; due to fair amount of spawning area in lower reach, this creek probably produces alot of pink and chum.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/15/81	Coho	Fry	a few		
	Cutthroat	Adults (8 inch & 7 inch)	2		

Survey(s) and Dates Conducted

C. Huntington, 6/15/81

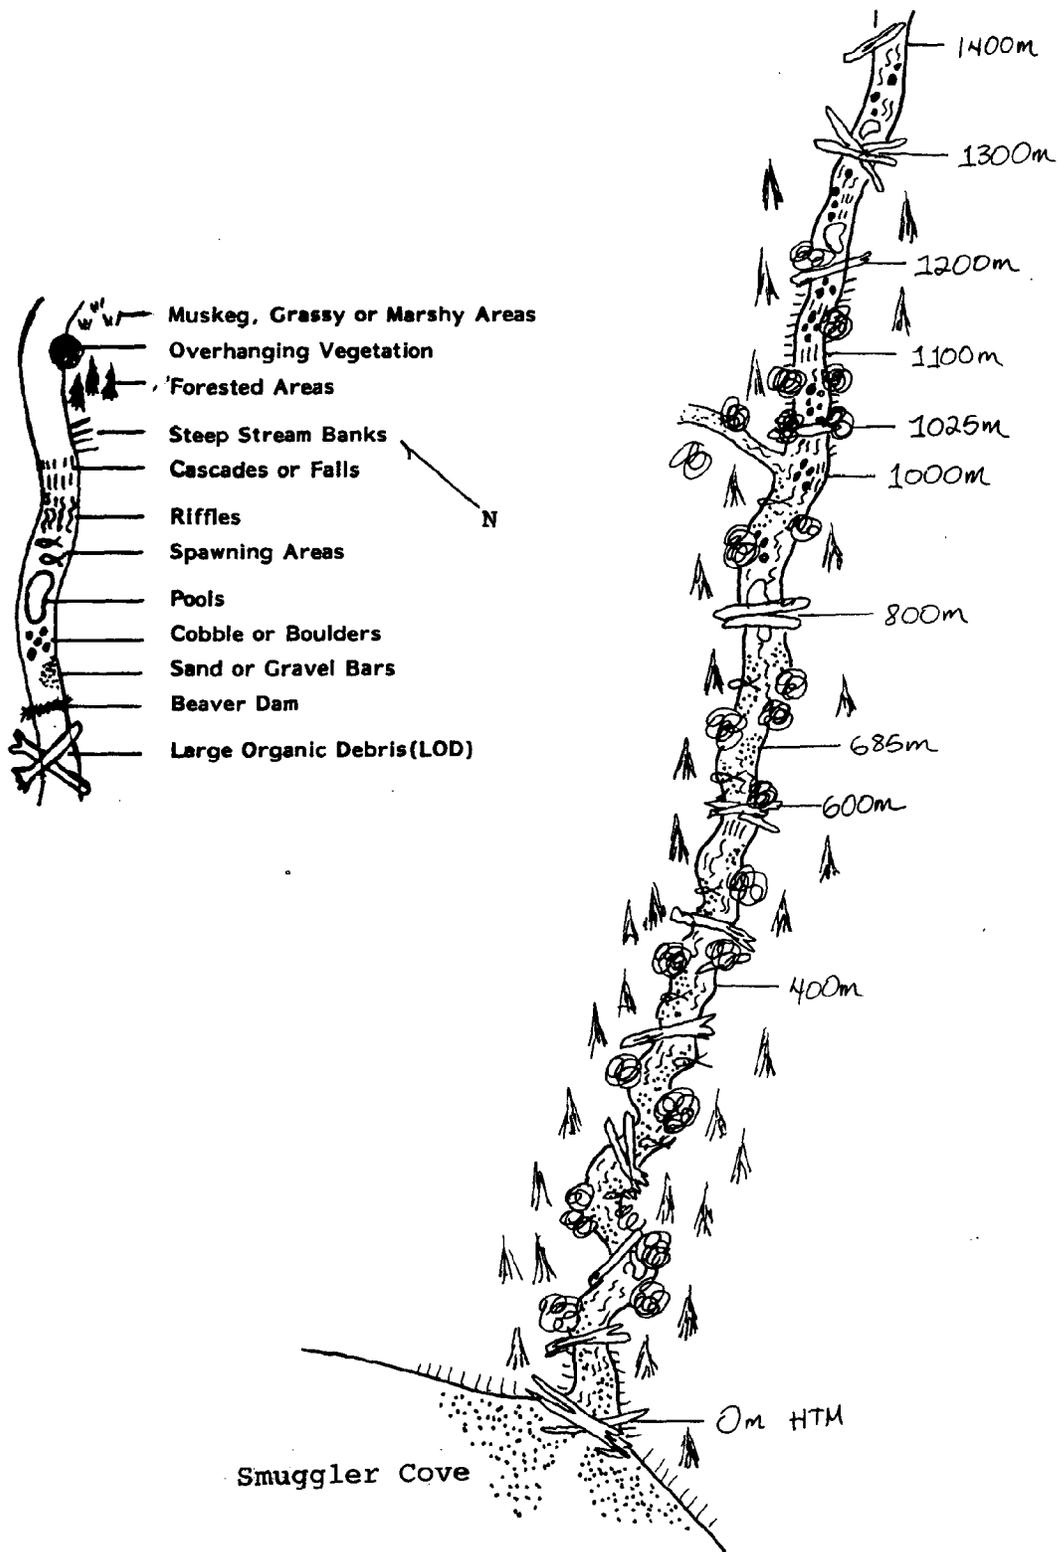

Recommended Escapement

A moderate amount of spawning area is available, and rearing area, so recommended escapements are 520 pinks, 34 chum, and 4 coho spawning pairs.

Potential Production Summary

Production potential, assuming a 10% egg-fry survival rate, is 1544 pinks, 170 chum and 23 coho returning to Annette Island.

Figure 19. NORTH SMUGGLER CREEK

Not In Scale

NORTH SMUGGLER CREEK

Watershed No. 101-03
Stat. No. 101-28-021

0m High Tide Mark (HTM), beach log jam.

0-400m Good spawning and rearing habitat, low gradient
LOD and overhanging cover.

600m .5m high passable debris jam with old redd just
above it.

685m Another old redd observed.

800m Log fall in creek; coho fry and adult trout here;
heavy algae growth occurs in side pools.

1000m Amount of rubble and boulder in channel increases
here. Tributary making up 35% of the total stream
flow enters here.

1025m Passable debris jam with coho fry below it.

1100m Passable bedrock chute.

1200m Passable slash and debris jam.

1300m LOD pile.

1400m Good rearing area continues (from 0m) but spawning
area is patchy. End of survey.

Spawning Area:

Intertidal	Limited to about 10m ²	
Above HTM	0-1000m	275m ² (mostly below 600m)
	1000-1400m	<u>25m²</u>
	Total	300m ²

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Yellow Hill Lake Creek	101-28-022	101-04
<u>Stream</u>	<u>Number</u>	<u>Geocode</u>

Abundant - mayflies, caddisflies and diptera observed.				
<u>Aquatic Invertebrates/Available Food Source</u>				
Scarce				
<u>Aquatic Vegetation</u>				
Mainly of muskeg and stunted timber - scarce.				
<u>Terrestrial Vegetation</u>				
60% in lower section, 30% due to banks, 30% due to brush; 30% shading near lake.				
<u>Shading</u>				
Limited - velocity is too high and creek is too steep in many areas; however, some is available in the				
<u>Extent and Quality of Rearing Area</u>				
braided channels.				

Reported and Suspected Use of Stream by Fish and Fishermen

Trout only use creek.
Use by Fish
 No known fishing activity.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Not a salmon stream - manage for cutthroat only; USEWS recommended stocking with rainbow - in 1973,
 they did stock.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
5/11/72	Cutthroat	Adult and Fry	A few	--	
1973	Rainbow	Fry	1000	--	Stocked in Yellow Hill Lake
6/15/81	Cutthroat	Fry	Several	--	

Survey(s) and Dates Conducted

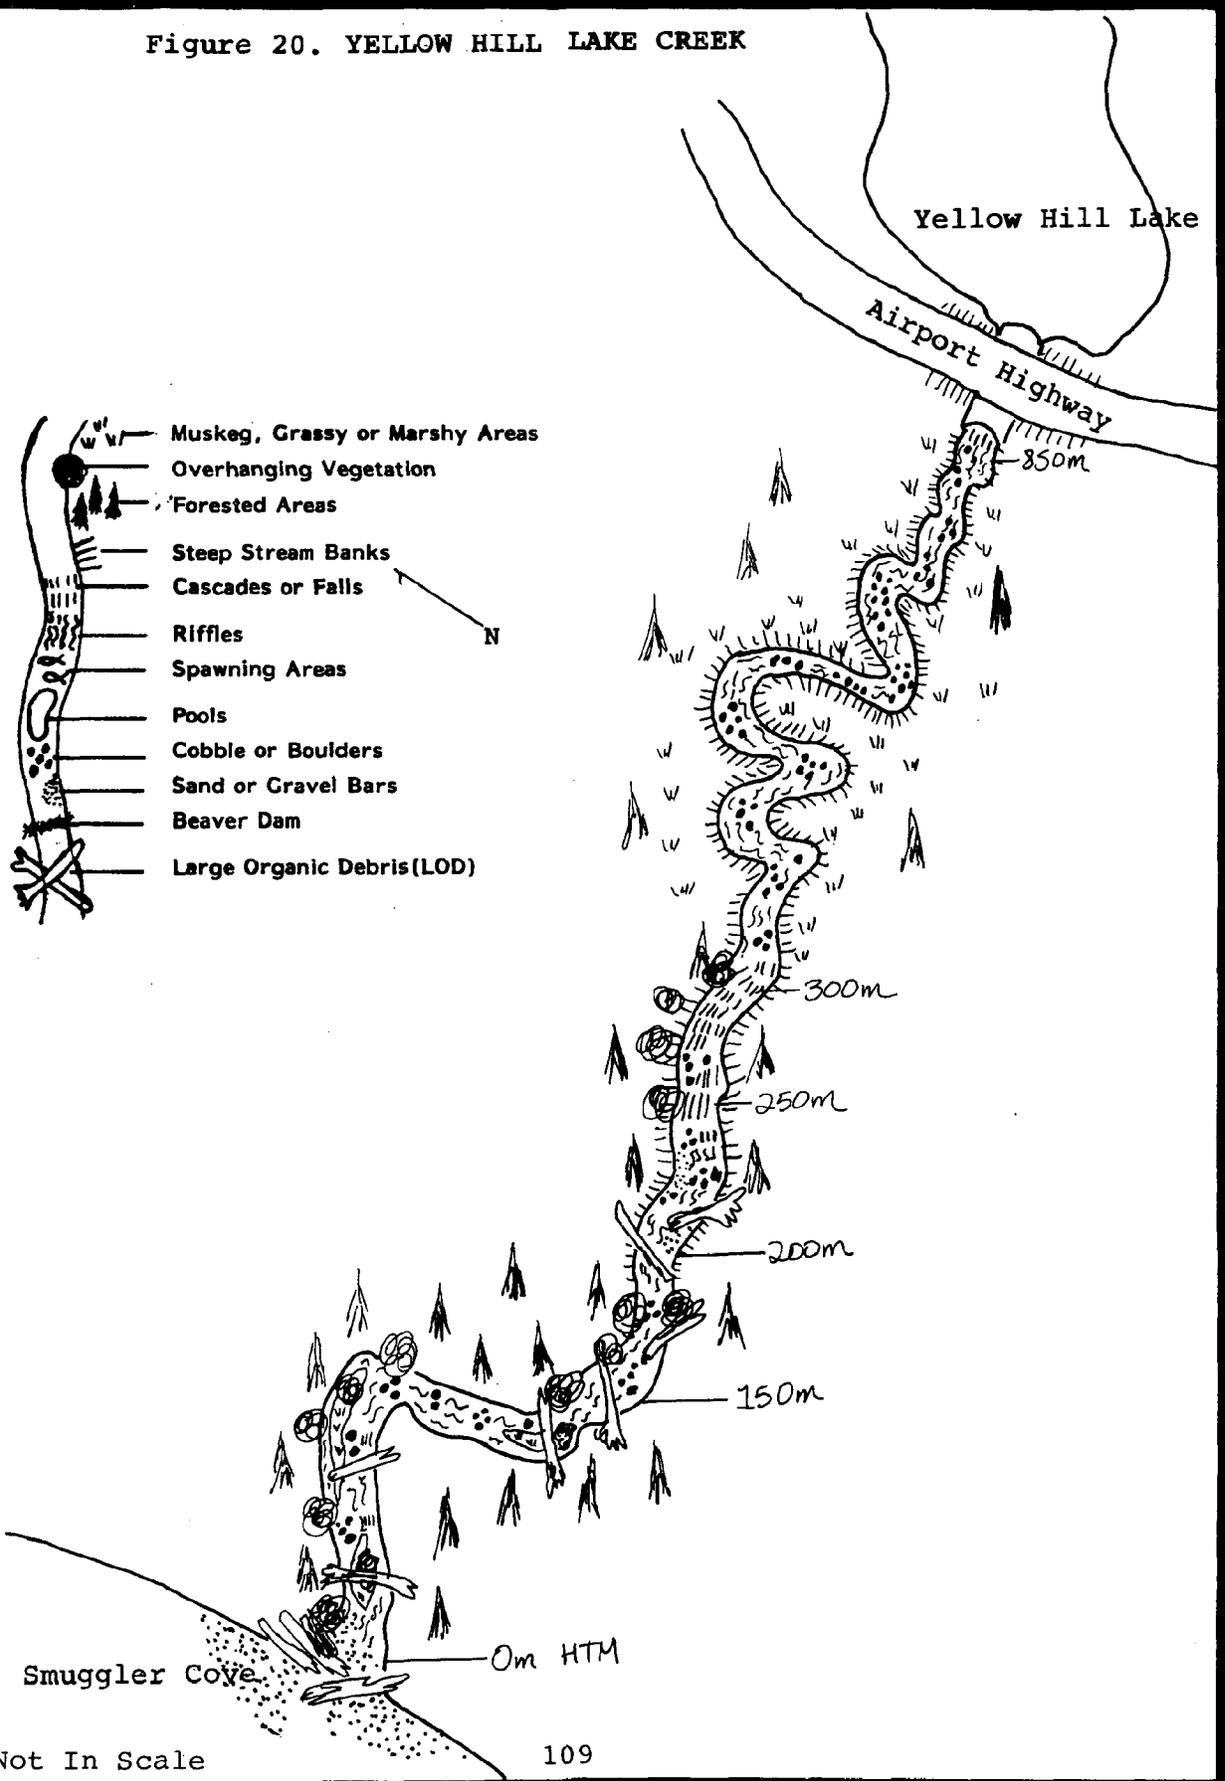

C. Huntington and J. Yuska, 6/15/81 and USFWS, 5/11/72

Recommended Escapement

No salmon production is expected, however, trout utilize this creek.

Potential Production Summary

Figure 20. YELLOW HILL LAKE CREEK

Not In Scale

YELLOW HILL LAKE CREEK

Watershed No. 101-04

Stat. No. 101-28-022

- 0m High Tide Mark (HTM), no intertidal gravels.
- 0-150m Average Stream Width (ASW) = 3m, stream braids with large cobble substrate (no gravel), some LOD in channel.
- 200-250m Bottom composition: 30% cobble, 60% boulders, 5% gravels, 5% fines. Stream has good cover and LOD, 60% shading, but moderate gradient (too steep for coho fry). ASW = 1.75m, Average Stream Depth (ASD) = .06m, at 250m, is an 8m cascade and probably barrier.
- 300-850m Creek meanders through muskeg, ASW = 1.0m, ASD = .08m, gradient is low to moderate and shading is 30% (20% by stream banks and 10% by vegetation). Bottom composition: 60% large cobble, 35% boulders, and less than 5% gravel. Cutthroat fry were observed in this stretch. Fish passage may be blocked by partially plugged road culvert at 850m.

Spawning Area: Limited, less than 10m² total area.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
------	---------	------	--------------	------	----------

No salmonids seen and no evidence of redds.

Survey(s) and Dates Conducted

J. Yuska, 6/15/81

Recommended Escapement

Due to the creek and gravel sizes, probably only pinks utilize this creek and recommended escapement is 32 pink spawning pairs.

Potential Production Summary

Due to poor gravel quality, 1.2% egg-fry survival rate assumed, production potential is only estimated at 11 pinks.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Smuggler Creek II	101-28-025	101-06
Stream	Number	Geocode
Flows W into Smuggler Cove, 300m long	Muskeg run-off	Forested muskeg flats.
Location	Origin	Watershed Type
6/15/81	300m - entire creek from High Tide Mark (HTM)	15 300m it runs into muskeg. Low
Date Surveyed	Section Surveyed	Barriers
--	.25 cfs / --	-- --
Ave. Gradient	Flow / Range	Ave. Velocity/Range
Steep - mud and rock banks with vegetation.	Stable	None
Streambank Composition	/ Stability	Tributaries

Water Quality

None taken	--	--	--	--	--	Brown	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO2	
--	--	--		Muskeg water				
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall					

Spawning Area

10% spawning gravel in a 50m stretch, otherwise, creek bottom is all fines (muskeg muck and silt) and

Overall Stream Bottom Composition

some bedrock.

Moderate with fines.

Gravel Compaction

At most 3m² available - minor production if any.

Spawning Area Available Above High Tide Mark (HTM)

None - mouth choked with LOD.

Intertidal Spawning Area

Rearing Area

Few pools

Pool/Riffle Frequency (P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Some composed of LOD, muskeg land bridges and some off channel areas.

Available Cover

Scarce

Aquatic Invertebrates/Available Food Source

Some moss and algae.

Aquatic Vegetation

Moss, salmonberry, currant, azalea, cedar, hemlock and shorepines.

Terrestrial Vegetation

Over 75% due to stream bank vegetation and canopy.

Shading

Limited - there is some good cover, but the creek is very small.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

No known use by fish.

Use by Fish

No known use by fishermen.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

There is a possible barrier at 120m from the mouth at a 2m falls; also at a bedrock cascade at 100m.

In addition, LOD and debris blockage at mouth acts as a barrier except at high tides and high flow. Pinks only, would probably use this creek, although production is probably minor.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
------	---------	------	--------------	------	----------

Survey(s) and Dates Conducted

J. Yuska, 6/15/81

Recommended Escapement

None are made due to the limited creek and spawning area size.

Potential Production Summary

Some may occur, but is not included in the total estimate at this time.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Smuggler Creek I		101-28-026	101-07	
Stream		Number	Geocode	
Flows W into Smuggler Cove, .4 mi long		Smuggler Lake	Forested muskeg flats.

Ave. Gradient	Flow / Range	Ave. Velocity/Range	Ave. Width/Range	Ave. Depth/Range
Mud, rock and sand with muskeg vegetation and				
root tangles - some LOD created channels./		Stable except at mouth		Two - no forks.
Streambank Composition	/ Stability	Tributaries		
		where erosion has occurred.		
Water Quality	6/9/72: 17.8C	13.9C	6.0	Clear / Slight
25m Above HTM	10.6C	13.5C	--	Clear / None
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity
Trace (6/9/72)	10.0ppm (6/9/72)	8.63ppm CaCO ₃ (6/9/72)		Resistivity = 4716 ohms/cm ³ (6/9/72)
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall	

Spawning Area

Trace rubble, trace cobble, 40% gravel, 25% pebbles, 25% sand, 10% silt and muck.

Overall Stream Bottom Composition

Some fines mixed in gravels.

Gravel Compaction

325m² available mainly on gravel bars - 5 old redds observed.

Spawning Area Available Above High Tide Mark (HTM)

None - indistinct channel clogged with LOD.

Intertidal Spawning Area

Rearing Area As flow increases, more riffle occurs,

p:r = 1:2 pools occur at bends and behind beaver dams. .15m / to .55m One is 1.8 x 7.5m in area/--

Pool/Riffle Frequency(P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Undercut banks, LOD and pools provide alot of cover.

Available Cover

Abundant - ephemeroptera, diptera, and trichoptera observed.

Aquatic Invertebrates/Available Food Source

Scarce

Aquatic Vegetation

Much of riparian vegetation is just thick forest understory of alders, berries, some muskeg plants, spruce and hemlock.

Terrestrial Vegetation

98% (70% from thick and tight riparian vegetation, the rest is from canopy and topography).

Shading

Extensive rearing area is available in LOD, pools, beaver ponds and in lake.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks, coho are known to use creek, chum may use it also.

Use by Fish

Some subsistence fishing occurs.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Stream is probably inaccessible to fish except during periods of high flow, because of a sand/silt and LOD bar at the mouth (creek seeps through it). Gravel not too good for anything but Pinks, but coho obviously use creek - although their production is probably limited because of the small gravels.

Escapement counts are recommended, and fishing regulations also, if the creek proves to be underescaped.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/9/72	Coho	Fry	A few		Observed in lake (not counted).
	Pink	Adults			Not counted
6/15/81	Coho	Fry	Numerous		

Survey(s) and Dates Conducted

C. Huntington, 6/15/81 and USFWS, 6/9/72

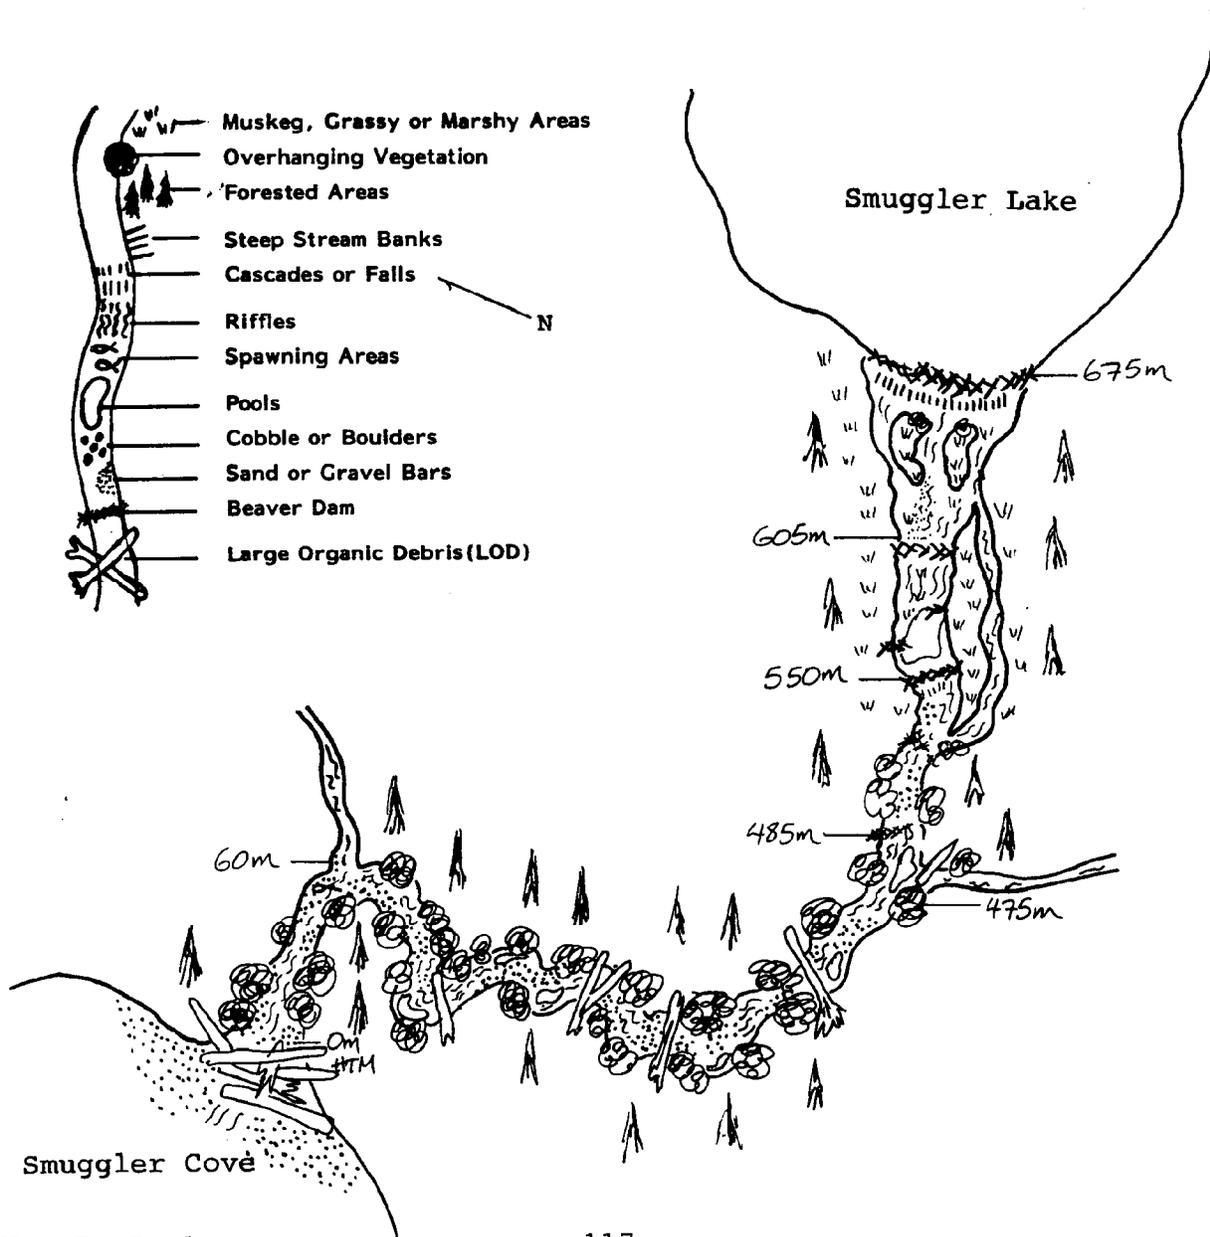

Recommended Escapement

According to the spawning area available and rearing area for coho, recommended escapements are: 540 pinks, 35 chum and 28 coho spawning pairs.

Potential Production Summary

The gravel is of poor quality, so a 1.2% egg-fry survival rate will be assumed. Potential production based on the above escapements are 200 pinks, 21 chum, and 20 coho returning to Annette Island.

Figure 21. SMUGGLER CREEK I

Not In Scale

SMUGGLER CREEK I

Watershed No. 101-07

		Other/Overall

Spawning Area

Mud, a few gravels and some boulders and rock.

Overall Stream Bottom Composition

Some with fines mixed in gravel.
Gravel Compaction

Limited to about 15m².

Spawning Area Available Above High Tide Mark (HTM)

None

Intertidal Spawning Area

Rearing Area

--

Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range

Provided by LOD, root tangles, beaver ponds and Lake (if salmonids use it).

Available Cover

Some blackflies and mayflies.

Aquatic Invertebrates/Available Food Source

Periphyton and filamentous algae abundant on rocks.

Aquatic Vegetation

Muskeg vegetation, stunted trees mainly and heavy riparian vegetation (berries and shrubs).

Terrestrial Vegetation

95%, (60% due to overhanging vegetation and 30% due to canopy).

Shading

Fair coho habitat exists, but creek is so small, production is probably limited to low numbers.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Coho utilize and perhaps a few pinks - trout also.

Use by Fish

No fishing known.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Creek of minor importance - limited spawning area available, but it does produce a few fish.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/12/73	None observed				
6/15/81	Coho	Fry	5		In small pond near mouth.

Survey(s) and Dates Conducted

C. Huntington, 6/15/81 abd USFWS, 6/12/73

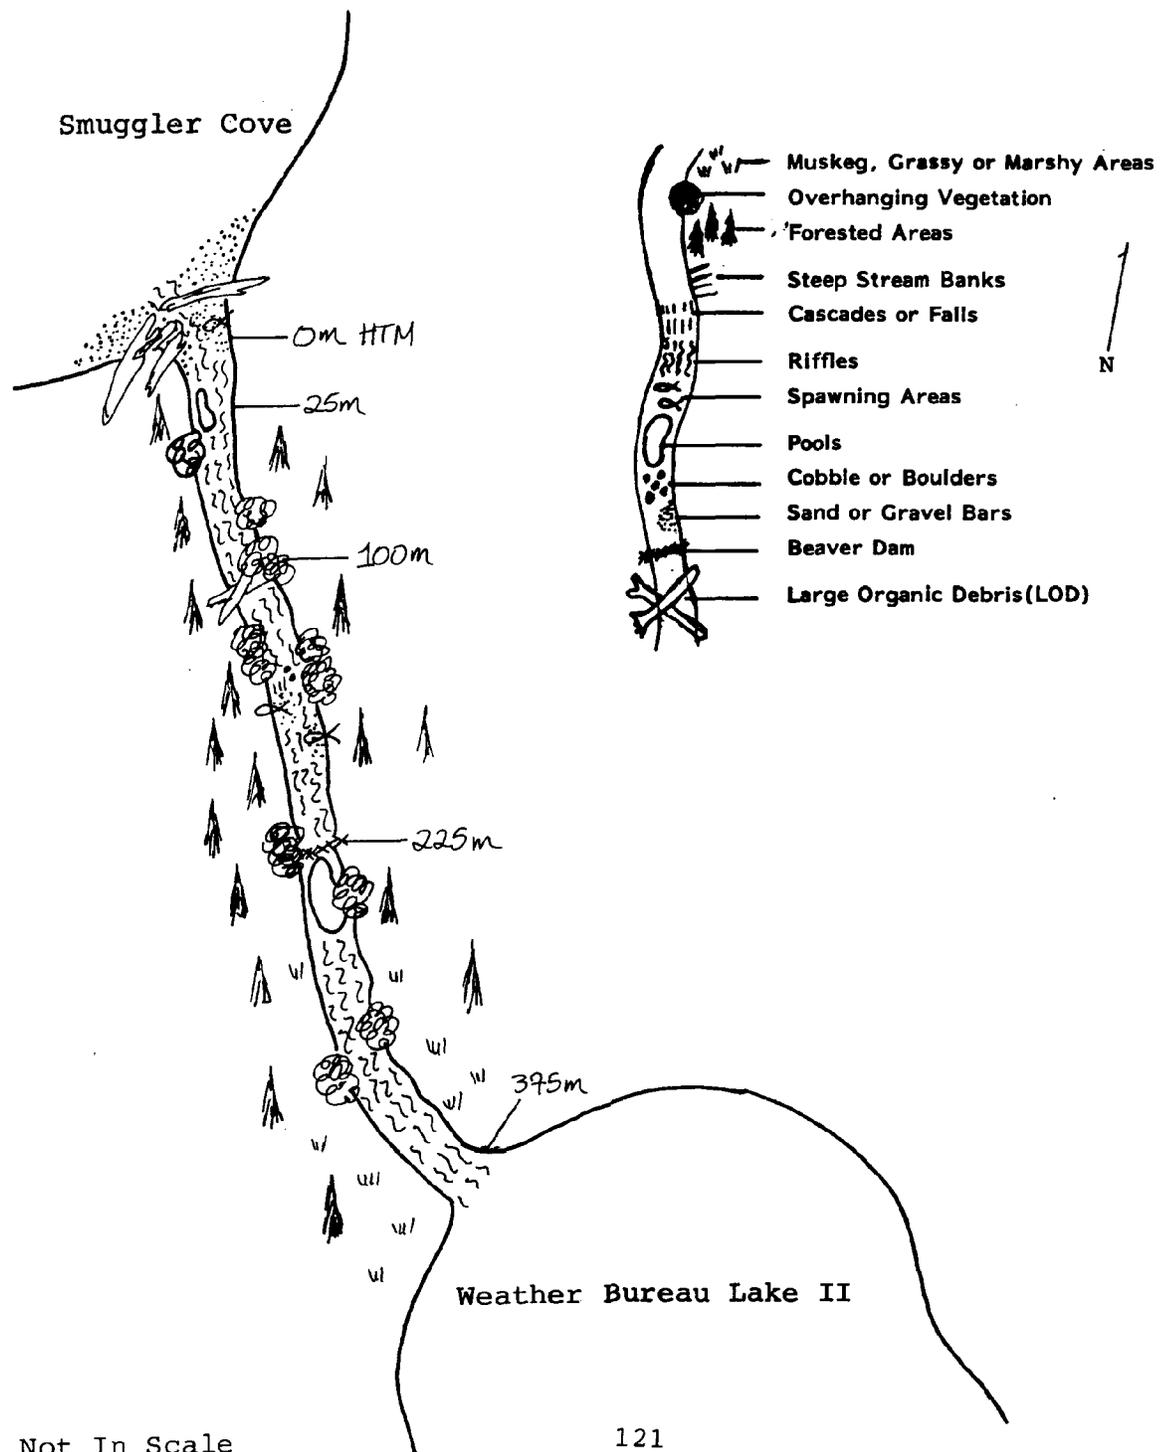

Recommended Escapement

Due to the limited spawning area available, but abundant rearing area, 2 coho spawning pairs could utilize this creek.

Potential Production Summary

Potential production, based on the poor quality of gravels is only a couple coho returning.

Figure 22. WEATHER BUREAU CREEK

Not In Scale

WEATHER BUREAU CREEK

Watershed No. 101-08
Stat. No. 101-28-027

- 0m High Tide Mark (HTM), logs piled up here; no available intertidal spawning area.
- 25m 5 coho fry observed in a small pond; lots of algae on rocks.
- 100m Stream goes under a root tangle of a live tree and the channel above here is not well-defined.
- 225m .8m high beaver dam here, may be a barrier.
- 375m Weather Bureau Lake II

Spawning Area: Limited, no intertidal area.

Above HTM is only about 15m² spawning area.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Gillnet Creek		101-28-028	101-09
Stream		Number	Geocode
Flows NW into Nichols Passage, 1.5 mi long.		Muskeg ponds and run-off.	Gently rolling muskeg and forested hills.

Lower reach: 50% gravel, 15% pebble, 15% cobble, 10% sand, 5% silt, 5% rubble, 30% of creek is beaver pond
Overall Stream Bottom Composition Bed material is very angular in
 with muck/silt/organic matter substrate. places - not great quality.

Gravel Compaction

LOD provides some trapped gravels and excellent spawning below 1150m (first 500m of creek) - 625m² area

Spawning Area Available Above High Tide Mark (HTM)
 total is available above HTM (fair quality gravels).

150m² is available near very large estuarine rearing area.

Intertidal Spawning Area

Rearing Area

Many pools - produced by LOD and beaver dams. .30m / to 1m -- --

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
LOD influence strong in areas forming pools; along with LOD, undercut banks, root wads and deep ponds provide abundant cover.		

Available Cover

Abundant in areas - caddisflies and diptera observed.

Aquatic Invertebrates/Available Food Source

Filamentous algae, periphyton and mosses are abundant.

Aquatic Vegetation

Muskeg vegetation (berries and shrubs) and old growth timber (cedar, hemlock, spruce).

Terrestrial Vegetation

95% in lower reach; 30% of creek is an open beaver pond area.

Shading

Excellent coho habitat in lower reaches with abundant LOD, beaver ponds and a large estuarine rearing

Extent and Quality of Rearing Area

area is available in addition.

Reported and Suspected Use of Stream by Fish and Fishermen

Coho, cutthroat, and rainbow utilize creek; pink and chum may also.

Use by Fish

No known use by fishing except possibly some commercial fishing (gillnetting) near the mouth.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Escapement counts are recommended. No habitat improvement is recommended; the creek probably already

produces adequate numbers (a moderate amount of production).

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/15/81	Cutthroat	Fry		Abundant	
	Rainbow	Fry		Abundant	
	Coho	Fry		Abundant	

No escapement counts ever conducted.

Survey(s) and Dates Conducted

C. Huntington, 6/15/81

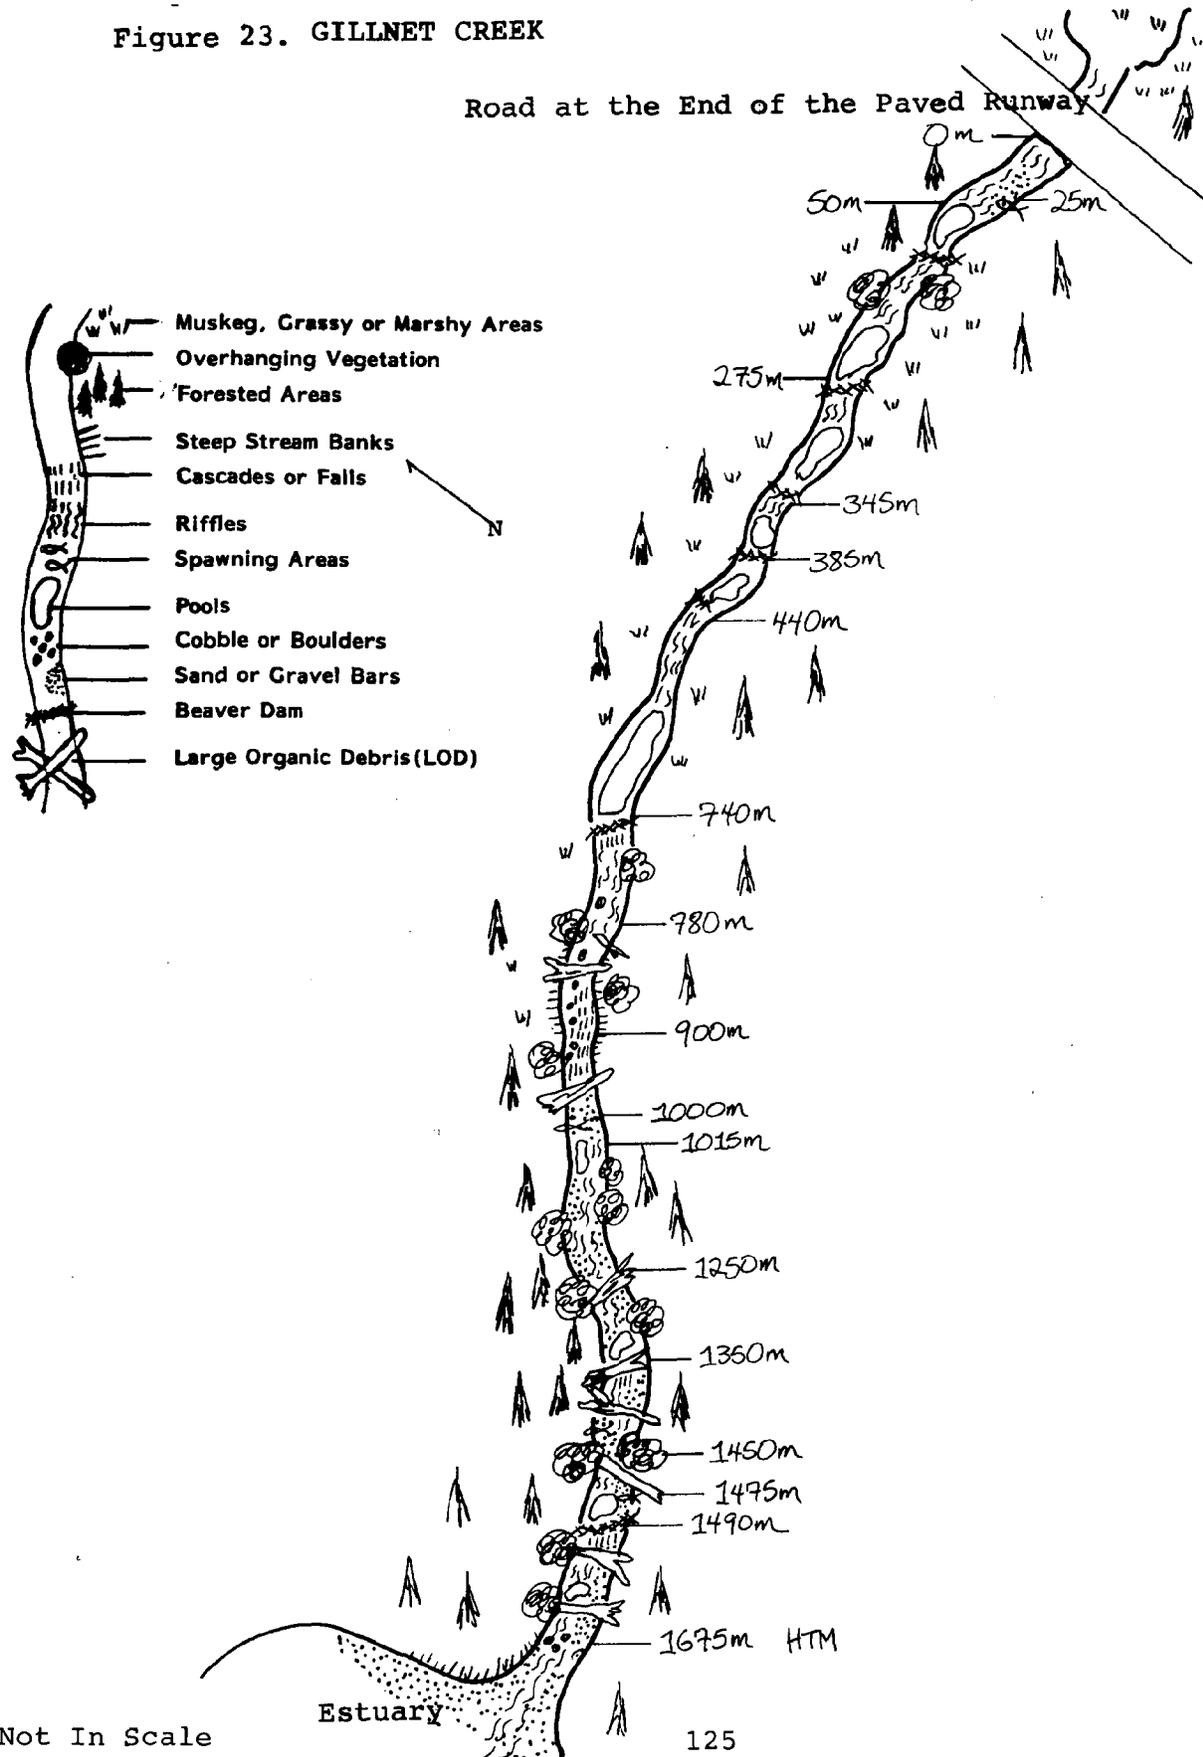

Recommended Escapement

Due to the extensive intertidal and freshwater spawning areas available, the following recommendations can be made: 1300 pink, 85 chum and 10 coho spawning pairs could utilize this creek.

Potential Production Summary

Gravel is of fair quality so a 10% egg-fry survival rate will be assumed. 3861 pinks, 421 chum and 56 coho could return to Annette Island as a result of production from this creek.

Figure 23. GILLNET CREEK

GILLNET CREEK

Watershed No. 101-09
Stat. No. 101-28-028

0m Blocked culvert (creek runs under dirt road at the end of the paved runway).

25m 5m² patchy spawning area, angular gravels and low velocity flow; juvenile salmonid observed here.

50m Upstream end of beaver dam.

275m .4m high beaver dam with 225 x 5m pond.

345m .35m high beaver dam with 70 x 4m pond.

740m 1m high beaver dam (passable at high flow) with 300 x 5m pond.

780m Two washed out beaver dams, creek begins to flow more freely. Bottom composition is bedrock, boulders, rubble and some cobble with alot of algae and moss occurring.

900m Bedrock banks predominate from 780m.

1000m First spawning gravel patch since below culvert, 8m² area, angular gravels with cobbles and pebbles.

1015m Coho fry in side pools, pools average .25m deep with a .5m maximum depth.

1250m Suspected old redd found, Average Stream Width (ASW) = 3m, Average Stream Depth (ASD) = .15m.

1350m LOD influence strong forming pools and providing cover - forest surrounding area is old growth.

1450m Cutthroat rainbow, and coho fry seen here in abundance.

1475m Suspected old redd here.

1490m Beaver dam, .35m high, with a small pond.

1675m High Tide Mark (HTM). Intertidal spawning area opens up into a large estuarine rearing area.

Spawning Area:

Intertidal 150m² total area

Above HTM 625m² (Excellent spawning areas below 1150m, in first 500m of stream.)

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Canoe Cove Creek I		101-28-029	101-10
Stream Flows SW in N. Canoe Cove, about 1.5 mi long.		Number Everetts Lake and muskeg run-off.	Geocode 71 acres in area - Gently rolling hills with muskeg and forested areas.
Location	500m above High Tide	Origin	Watershed Type
6/22/81	Mark (HTM)	None	Low flow +3 ft
Date Surveyed	Section Surveyed (5/25/72)	Barriers	Stage
1.5%	3 cfs / up to 5 cfs	Moderate - 1 fps up to 2 fps.	1m / to 3m
Ave. Gradient	Flow / Range	Ave. Velocity/Range	Ave. Width/Range
Vegetated soil banks and rocks (some steep banks)/	Fairly stable	--	--
Streambank Composition	/ Stability	Tributaries	

Water Quality 5/25/72:	11.1C	9.4C	7.0	Turbid water	Brown	--	3.6ppm
--	20.0C	14.0C	--	Clear / None	Brown	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO₂
Trace (5/25/72)	12.5ppm (NaCl)	106.98ppm (5/25/72)		Dissolved Solids - CaCO ₃ = 10.7ppm (5/25/72)			
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				
	(5/25/72)						

Spawning Area

In first 500m: 20% gravels, 35% pebbles, 20% sand, 10% cobble and boulders, 5% bedrock.

Overall Stream Bottom Composition

Some occurs, gravels are of fair quality.

Gravel Compaction

Approximately 33m² is available - spawning area may be limited due to the narrowness of the stream.

Spawning Area Available Above High Tide Mark (HTM)

75m² total area available (again may be limited because of creek narrowness).

Intertidal Spawning Area

Rearing Area Pools occur in 60% of the entire creek area (many due to beaver activity).

.3m / --- 3 x 3.6m / --

Pool/Riffle Frequency (P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Provided by undercut banks, some LOD, overhanging vegetation - a moderate amount.

Available Cover

Sparse - but diverse: mayflies, midges, stoneflies, caddisflies, ephemeroptera, diptera.

Aquatic Invertebrates/Available Food Source

Moderately abundant moss on rocks and abundant filamentous algae.

Aquatic Vegetation

Huckleberry, salal, mosses, terrestrial grasses, chocolate lilies, skunk cabbage and a few alders; cedar and hemlock canopy.

Terrestrial Vegetation

From 0-200m: 50% shading (40% due to vegetation, 10% due to banks). 200-500m: 75% shading, all due to shrubs and herbaceous vegetation.

Shading

Moderate amount is available in LOD, under banks and pools (some formed by old beaver dams).

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, coho and cutthroat are known to use creek.

Use by Fish

No know use by subsistence or sport fishermen.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

No habitat improvements are recommended. Stream produces a moderate amount of salmonids.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
5/25/72	Coho	Fry	710		
	Pink, chum and coho adults have been observed in the past.				
6/22/81	Cutthroat	8 cm	1		Seen near creek mouth.

Survey(s) and Dates Conducted

J. Yuska, 6/22/81, and USFWS, 5/25/72

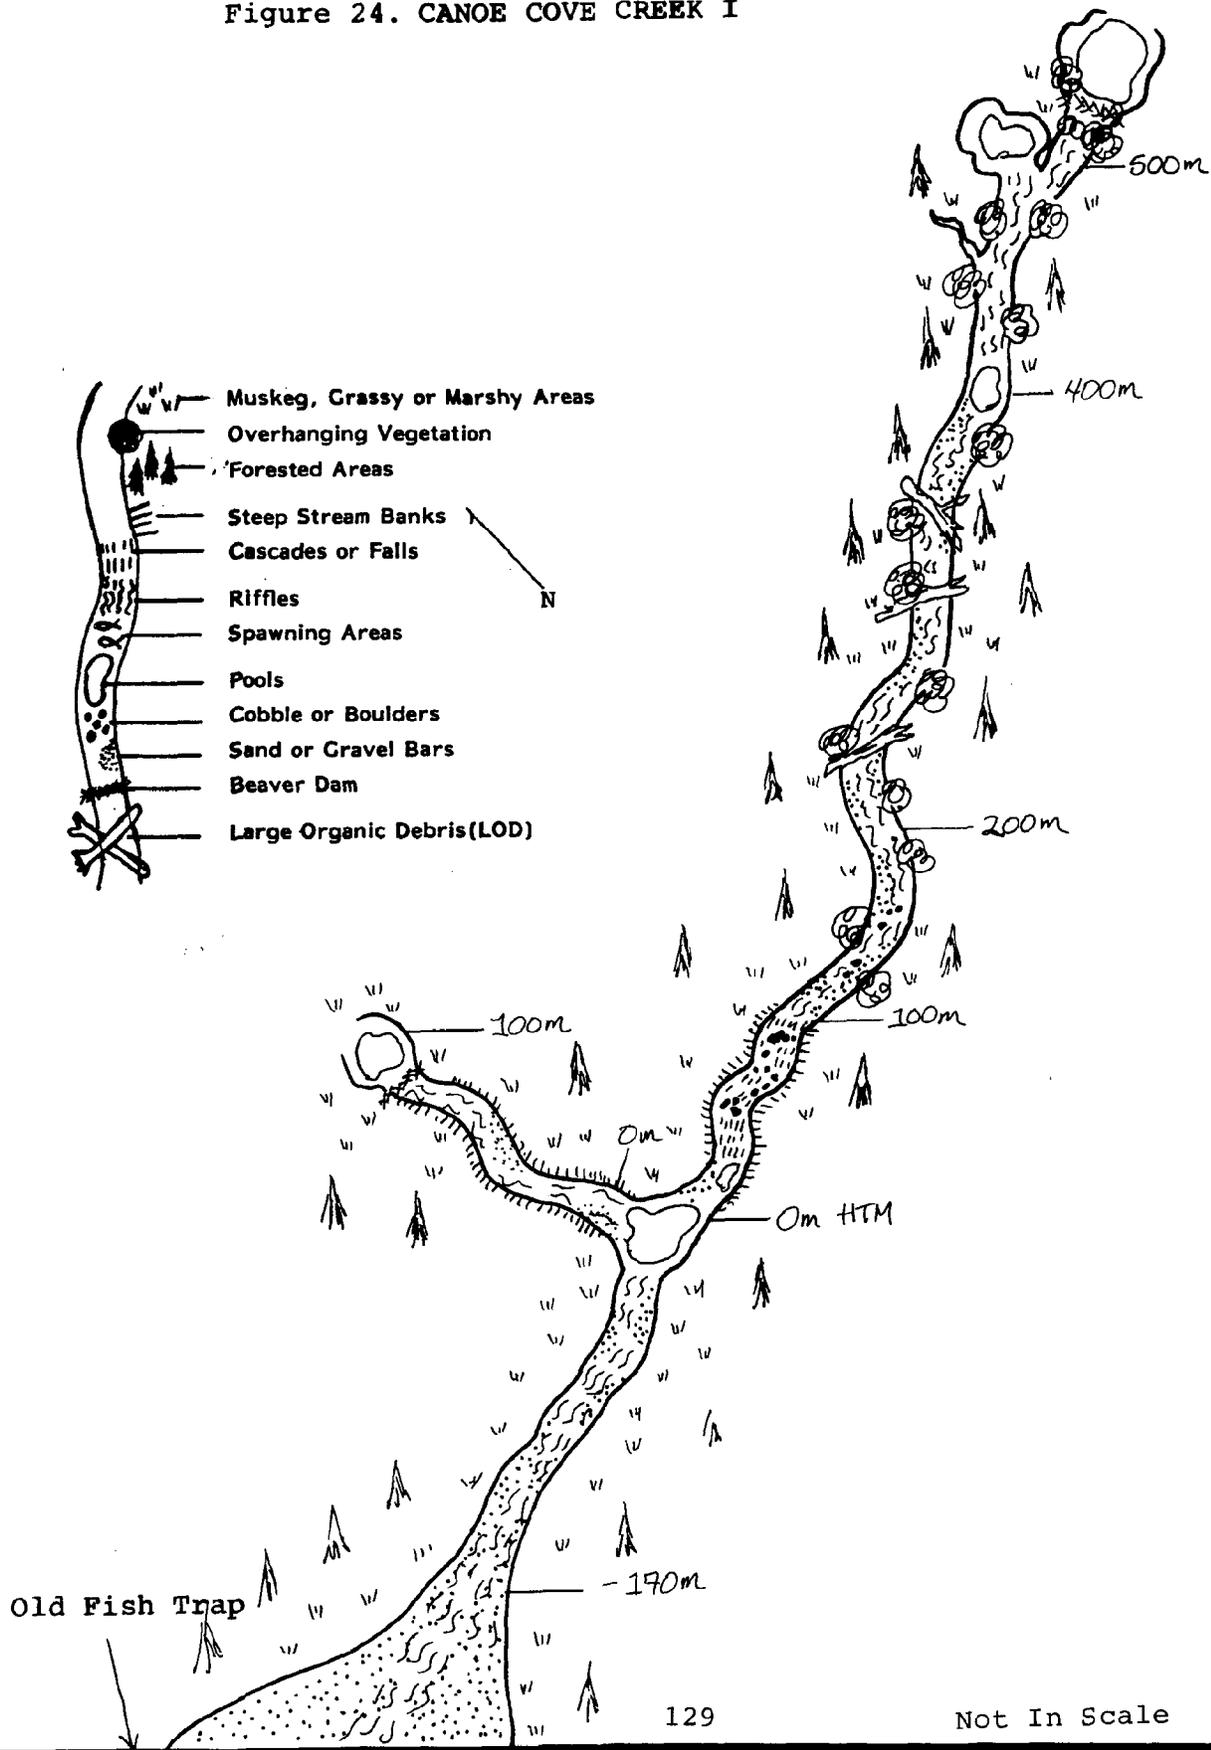

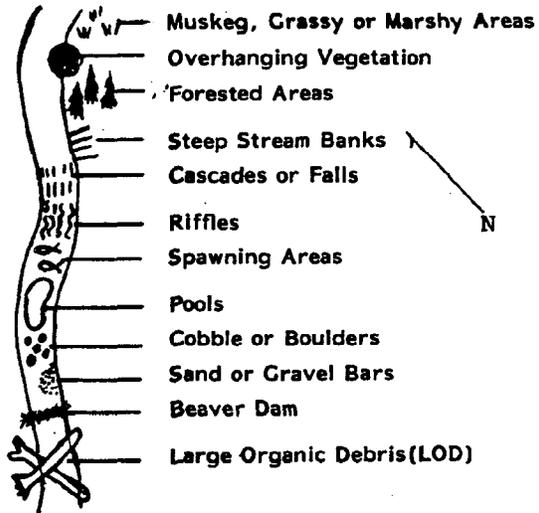

Recommended Escapement

According to spawning area available, the following recommendations can be made: 142 pinks, 9 chum and 2 coho spawning pairs.

Potential Production Summary

Gravels are of fair quality so a 10% egg-fry survival rate will be assumed. 422 pinks, 45 chum, and 11 coho could return to Annette Island as a result of production from this creek.

Figure 24. CANOE COVE CREEK I

CANOE COVE CREEK I

Watershed No. 101-10
Stat. No. 101-28-029

- 170-0m Average Stream Width (ASW) = 5m, 10% usable gravels (75m² spawning area total). High Tide Mark (HTM) at 0m.
- 0m At HTM, a large 100m tributary, ASW = .5m with a bottom of 20% gravels, 40% pebbles and 40% sand, enters; it flows over a beaver dam at 100m up and ends in a large intertidal pool 25m in diameter; there is a 10m² available spawning area in the tributary.
- 5m Adult cutthroat trout observed.
- 0-100m Cascades over bedrock (less than 5% gravel) possible velocity barrier for pinks and chum, with 1m high steep banks.
- 100-200m ASW = .75m, ASD = .05m. Bottom composition: 20% gravels, 40% pebbles, 20% sand and 10% cobble, 15m² available spawning area.
- 200-400m ASW = .75m, less gravels - 10% gravels (7.5m² available spawning area); moss and algae abundant in this section with some LOD; at 400m is a pool 4 x 1.5m.
- 400-500m ASW = .5m, ASD = .15m, with less than 5% gravels; 75% shading from 200m; water becomes stagnant at 500m - it is flowing out of muskeg ponds. (End of Survey)

Spawning Area:

- Intertidal 75m² area total
- Above HTM 33m² approximate total area

Spawning Area

--

Overall Stream Bottom Composition

Poor gravels quite a bit due to
fines in gravel.
Gravel Compaction

60m² of marginal quality spawning area.

Spawning Area Available Above High Tide Mark (HTM)

Substrate too fine below -25m to use, 75m² marginal quality area from 0 to -25m.

Intertidal Spawning Area

Rearing Area

Few pools or riffles.
 -- | -- | -- | -- || **Pool/Riffle Frequency (P:R Ratio)** | **Ave. Pool Depth/Range** | | **Ave. Pool Size/Range** | |
Some available due to overhanging vegetation, but it is limited.				
Available Cover				
Scarce - diptera observed.				
Aquatic Invertebrates/Available Food Source				
Some moss and filamentous algae - sparse.				
Aquatic Vegetation				
Salal, skunk cabbage, ferns, vanilla leaf, azalea, mosses; canopy is cedar and shorepines.				
Terrestrial Vegetation				
Intense due to brush and trees (80%).				
Shading				
Limited - poor gravels and a fast velocity - not alot of cover is available.				
Extent and Quality of Rearing Area				

Reported and Suspected Use of Stream by Fish and Fishermen

No known use of stream by fish.

Use by Fish

No known use of stream by fishermen.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Limited use, if any, by pinks only due to fines in gravels and low pH. Any fish entering creek are probably strays; no improvements are recommended. Also possible debris and topographic barriers exist.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/19/81	None seen.				

Survey(s) and Dates Conducted

J. Yuska, 6/19/81 and USFWS, 9/8/71

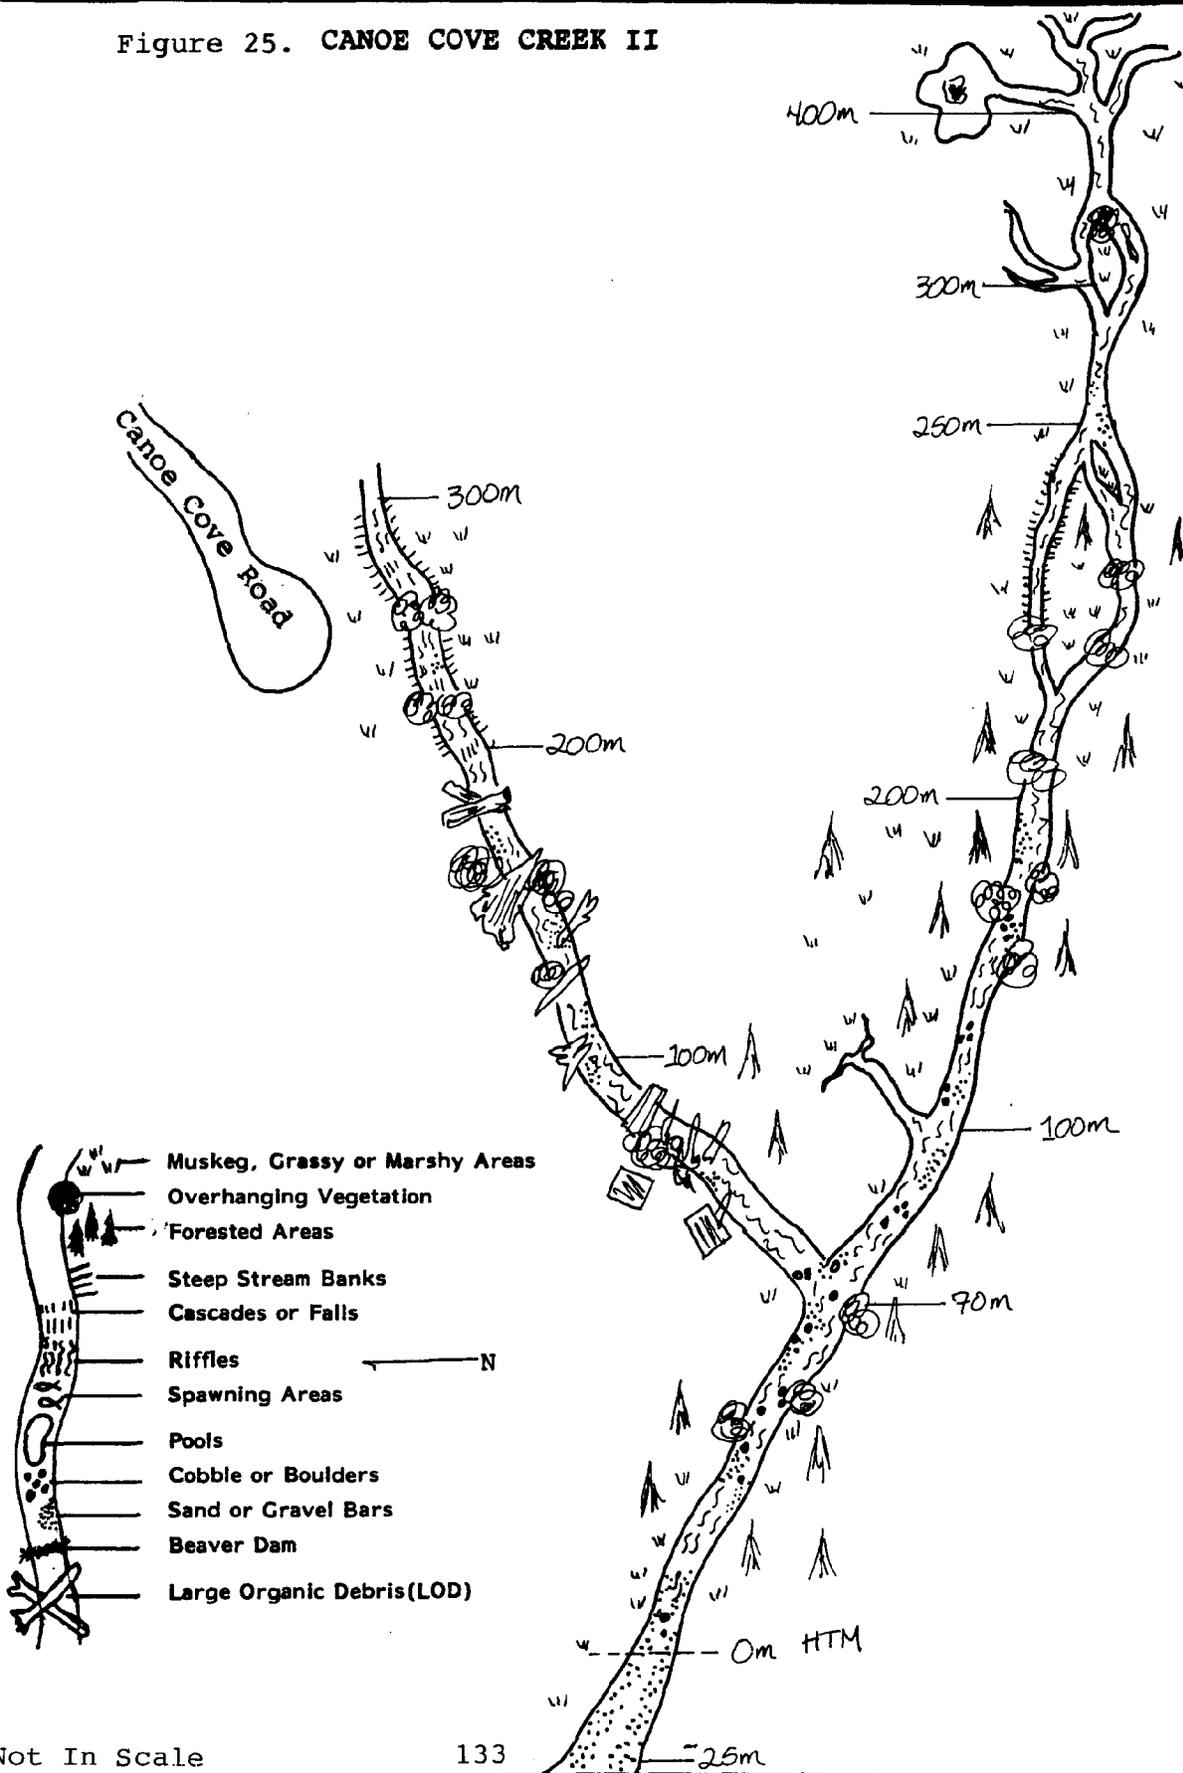

Recommended Escapement

Due to the fine gravels, probably only pinks would utilize this creek, with a recommended escapement of 233 spawning pairs based on available area.

Potential Production Summary

Due to the poor gravels, a 1.2% egg-fry survival rate is assumed, and only 83 pinks are estimated to return given the above escapement.

Figure 25. CANOE COVE CREEK II

Not In Scale

CANOE COVE CREEK II

Watershed No. 101-11
Stat. No. 101-28-030

-25-0m Average Stream Width (ASW) = 6m, 60% usable gravels (approximately 75m² spawning area).

-70m Creek flows over boulder and cobble; tributary enters at 70m.

0-300m (Tributary)

ASW = .5m, spawning gravel is approximately 10% (10m² available area); debris jams scattered from 0-200m, caused by old World War II structures fallen into creek - may be okay coho rearing habitat. Above 200m, stream gradient increases and creek becomes narrow with no gravels, at 300m, creek flows under and into the muskeg and is within 100m of the end of the Canoe Cove dirt road.

0-100m (Main Channel)

ASW = 2.5m, ASD = .06m, bottom is 20% gravels, 40% fines and 40% boulder and cobble, (approximately 45m² of spawning area is available).

100-200m ASW = 1m, 10% gravels are present (10m² spawning area). At 200m, stream splits into several channels with less than 5% gravels and alot of fine sediment, creek flows under muskeg "land bridges" that may be barriers to migration.

200-300m Many undercut banks, with a possible old redd at 250m in one small gravel bar. Stream splits again at 300m with less than 5% gravels.

300-400m Gradient is increasing and stream is still splitting into muskeg.

Spawning Area:

Intertidal 75m² area total

Above HTM Approximately 65m² of marginal quality spawning area.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Canoe Cove Creek III (S.E. Creek)	101-28-031	101-12
Stream	Number	Geocode
Flows NW into So Canoe Cove, 1 mile long. Muskeg pond and run-off.		
Location	Origin	Watershed Type
6/19/81	Entire length from low tide to ponds.	Muskeg flats with stunted timber stand. 60 acres in area.
Date Surveyed	Section Surveyed (6/19/81)	Flood Height
3%	Less than 1 cfs up to 1 cfs	--
Ave. Gradient	Flow / Range	Ave. Depth/Range
	.5 fps / --	.25m / --
Channel poorly defined in places and heavily influenced by LOD./Unstable. None

Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall			

Spawning Area

50% rubble, 30% sand, 20% boulder.

Overall Stream Bottom Composition

Some due to sand.
Gravel Compaction

Very little - salmon probably cannot reach the pond because of low flow and beaver dams.

Spawning Area Available Above High Tide Mark (HTM)

None

Intertidal Spawning Area

Rearing Area

Pools in 40% of the stream.

Pool/Riffle Frequency (P:R Ratio)	.35m / .6m	3.6 x 1.2m / --
Some in pools.	Ave. Pool Depth/Range	Ave. Pool Size/Range

Available Cover

Moderately abundant. Odonata and ephemeroptera observed.

Aquatic Invertebrates/Available Food Source

Scarce.

Aquatic Vegetation

Muskeg vegetation; stunted trees and heavy riparian vegetation.

Terrestrial Vegetation

Intense - about 40% due to riparian vegetation and 60% due to canopy.

Shading

Very little is available.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Probably no fish use this creek.

Use by Fish

No fishing known.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Low acidity, poorly defined channel, low flow and lack of gravels make this creek unusable by salmon.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
7/17/79	Unidentified Salmonids	Fry		Not counted	Observed; however, station station was intertidal - so they could be from another creek.

None seen or expected above HTM.

Additional Water Quality Data:

Flow: 7/17/79 - .09cfs 8/23/79 - .07cfs 9/20/79 - .59cfs
Temp (Water): 7/17/79 - 9.0C 8/23/79 - 14.8C 9/20/79 - 11.0C
D.O.: 7/17/79 - 11.5ppm 8/23/79 - 8.4ppm 9/20/79 - 10.4ppm
Conductivity (ohms/cm²) 7/17/79 - 8/23/79 - 7000 9/20/79 - 55
Other - Water color was dark brown and sampling station was found to be intertidal.

Survey(s) and Dates Conducted

C. Huntington, 6/19/81, USFWS, 8/24/72, and Pacific Rim Planners, Inc., 7-9/1979

Recommended Escapement

No recommendations for escapement are made due to the lack of spawning areas.

Potential Production Summary

None made.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Hidden Cove Creek	101-28-032	101-13
Stream	Number	Geocode
Flows N into S Canoe Cove, .2 miles long./ Muskeg ponds, springs and run-off. Partially forested muskeg.		
Location	300m from High Tide	Origin
7/19/81	Mark (HTM) to muskeg.	Muskeg ponds at 300m.
Date Surveyed	Section Surveyed	Barriers
1%	.25cfs / --	Less than 1 fps - slow
Ave. Gradient	Flow / Range	Ave. Velocity/Range
Muskeg vegetation in mud and rock - well-defined		
channel stabilized by vegetation.		
Streambank Composition	/ Stability	Tributaries
		None - stream splits into muskeg at 300m.

Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

40% gravels, 40% fines and pebbles, 20% cobble and boulders.

Overall Stream Bottom Composition

Alot of fines mixed in - marginal quality gravels.

Gravel Compaction

.75m² of marginal quality gravels available.

Spawning Area Available Above High Tide Mark (HTM)

Some available - 170m² area of marginal quality gravels.

Intertidal Spawning Area

Rearing Area

Few pools and riffles.

Pool/Riffle Frequency (P:R Ratio)	--	--	--	--
	Ave. Pool Depth/Range	Ave. Pool Size/Range		
Limited				

Available Cover

Scarce

Aquatic Invertebrates/Available Food Source

Some algae, but not abundant.

Aquatic Vegetation

Skung cabbie, grasses and sedges, some herbs and stunted trees.

Terrestrial Vegetation

0-10% due to topography (banks).

Shading

Very little due to lack of cover and small size of stream.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

No previous record of use by fish.

Use by Fish

No fishing.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Pink salmon may use this creek, but their success is questionable. No improvements are recommended - this creek produces low numbers, if any, of salmonids.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
7/19/81	None seen				

Survey(s) and Dates Conducted

E. Biggs, 7/17/81

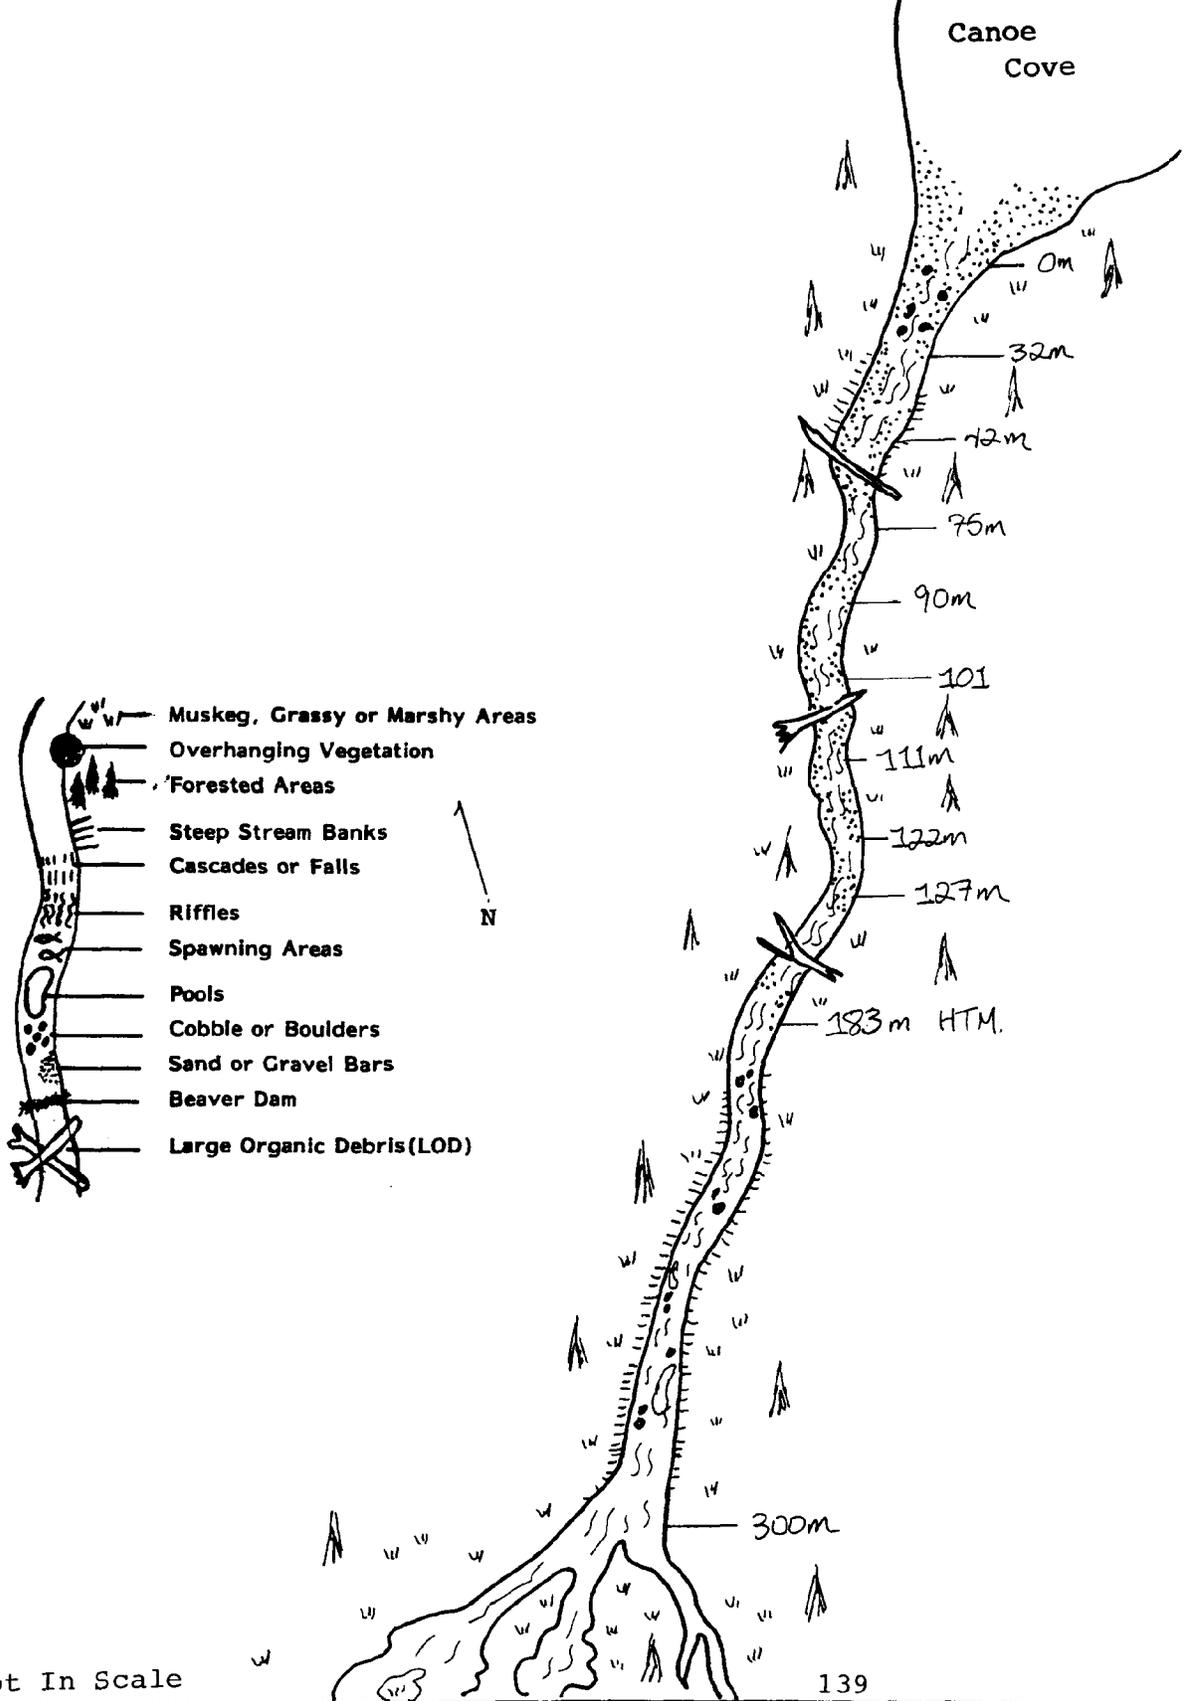

Recommended Escapement

Because of the fine gravels, only pinks could probably utilize this creek. Recommended escapement is 408 pink spawning pairs.

Potential Production Summary

Based on a 1.2% egg-fry survival rate (poor quality gravels) and the above escapement, only about 146 pinks would be expected to return to Annette Island from this creek.

Figure 26. HIDDEN COVE CREEK

Not In Scale

HIDDEN COVE CREEK

Watershed No. 101-13
Stat. No. 101-28-032

0-32m Average Stream Width (ASW) = 2m, intertidal gravels are about 50%.

32-42m Fine sediment mixed with gravel and pebbles, ASW = 9m with very slow flow (40m² marginal quality spawning area available).

42-75m ASW = 2m, mainly a pebble bottom with mud.

75-90m ASW = 2m, 75% spawning area (23m² area available).

90-101m Stream widens to ASW = 4m, (has alot of mud bottom) 25% spawning gravels (10m² area available).

101-111m ASW = 2m, 50% spawning gravels (10m² area available).

111-122m ASW = 3m, 75% spawning gravels (23m² area available).

122-127m ASW = 2m, 25% spawning gravels (2m² area available).

127-183m ASW = 5-6m, 10% spawning gravels, mostly a mud bottom (30m² area available). High Tide Mark (HTM) at 183m.

183-300m ASW = 1.5-2m, bottom is mostly pebble and boulders with areas of slow flow widened into pools (alot of of sedges and rushes on banks); some gravels available. At 300m, stream splits into muskeg.

Spawning Area:

Intertidal 170m² of marginal quality, but usable spawning area.
Above HTM 75m² total area.

Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall		
			Resistance = 33,000 ohms/cm ³ (5/24/72)		

Spawning Area

35% gravels, 35% fines, 30% cobbles and small boulders.

Overall Stream Bottom Composition

Some fines - fair quality gravels.
Gravel Compaction

500m² spawning area in creek sections with 20-40% gravels.

Spawning Area Available Above High Tide Mark (HTM)

Not Applicable

Intertidal Spawning Area

Rearing Area Pools - some large pools created by beaver activity and small pools by LOD.

Pool/Riffle Frequency (P:R Ratio)

Some LOD, undercut banks, beaver ponds and lake.

Available Cover

Some - diptera and trichoptera observed.

Aquatic Invertebrates/Available Food Source

Scarce

Aquatic Vegetation

Sisal, terrestrial grasses, huckleberry, ferns, azalea, mosses, devil's club, skunk cabbage; cedar dominant near creek, hemlock found away from stream.

Terrestrial Vegetation

75% due to canopy.

Shading

Limited because of moderate-fast velocity and very little LOD in channel; however, there are numerous

Extent and Quality of Rearing Area

undercut banks.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, coho and cutthroat utilize creek.

Use by Fish

Little to no fishing pressure known.

Use by Fishermen

Wildlife Present

None seen - evidence of beaver, mink and land otter.

Comments and Recommendations

No habitat improvements recommended. This creek does support a significant amount of coho fry and

chum and pink do use creek for spawning - an important production creek on Annette (combined with Annette Inn Creek).

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
11/24/71	Chum	Adult	2	-	(Probably too late to spot pinks).
	Coho	Adult	1	-	
6/19/81	Coho	Fry	1	-	

Escapement count combined with Annette Inn Creek Count

Survey(s) and Dates Conducted

J. Yuska, 6/19/81 and USFWS, 11/24/71 and 5/24/72

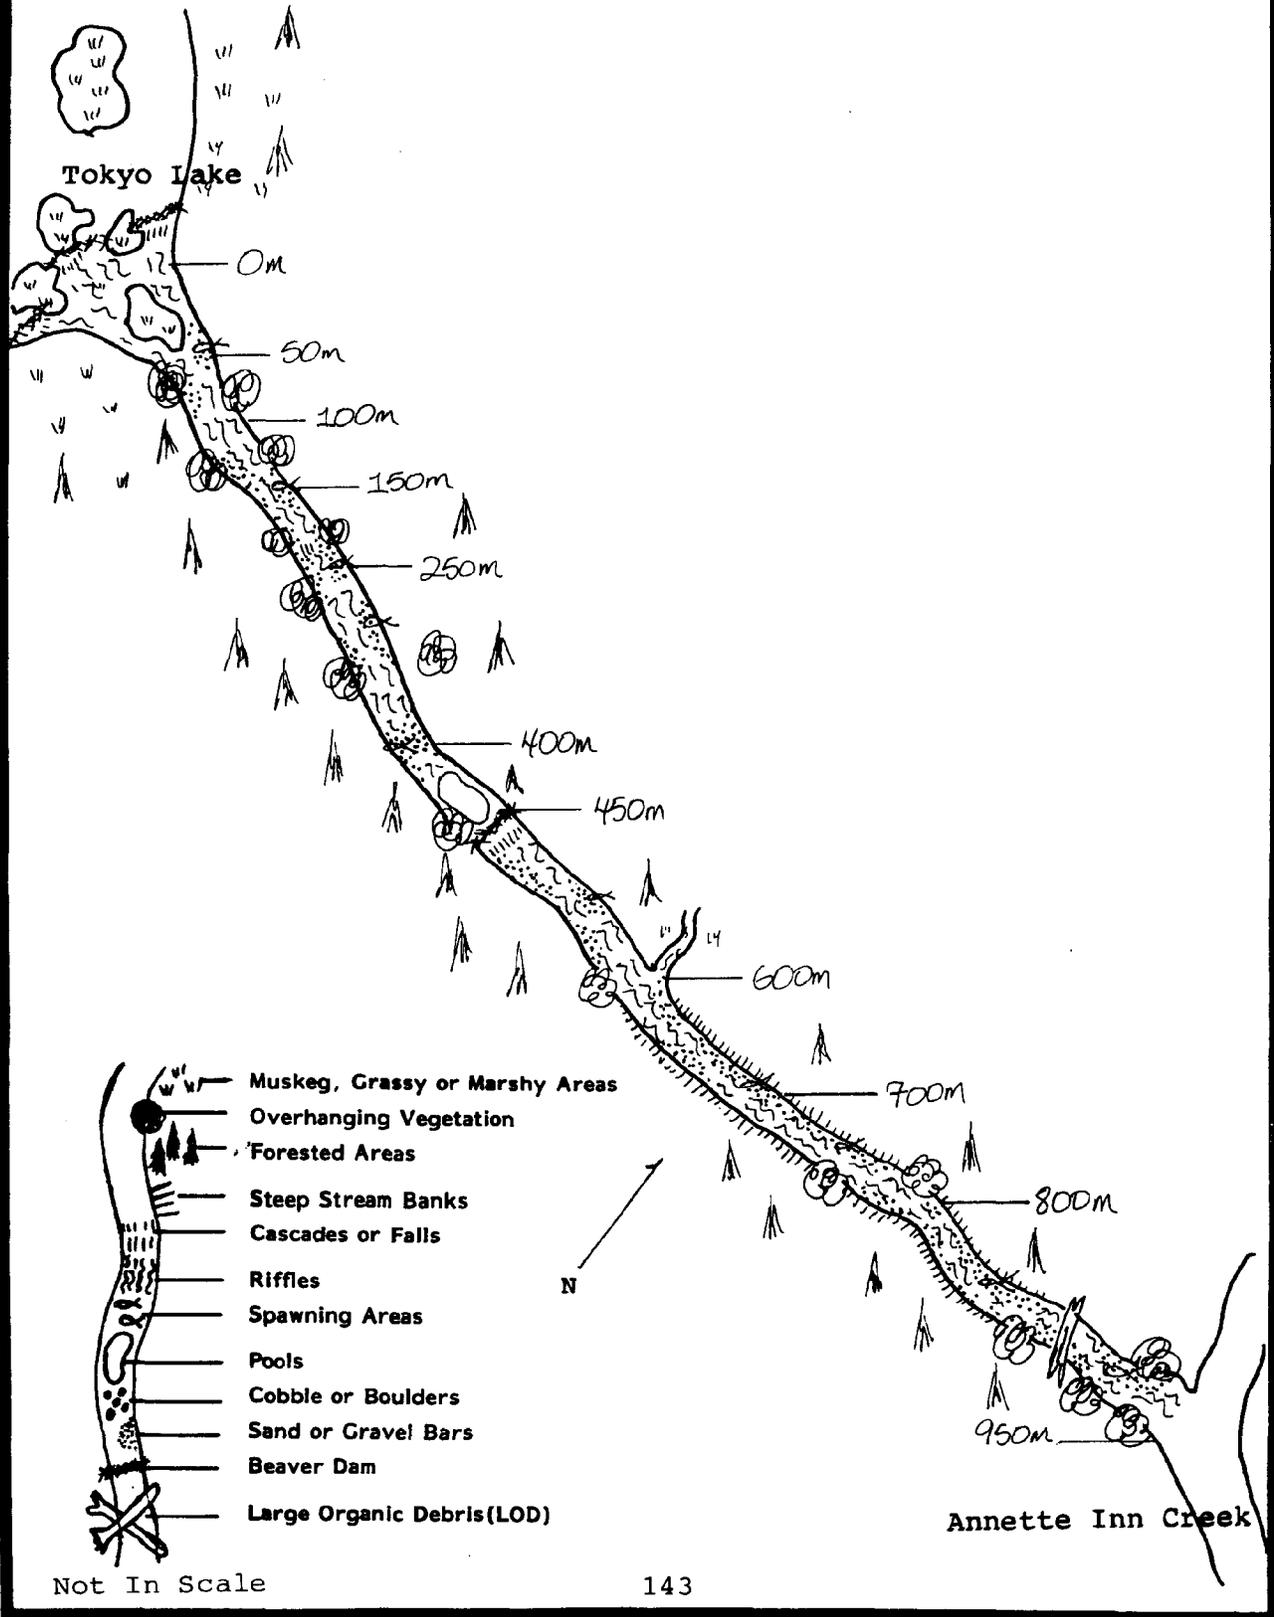

Recommended Escapement

Based on the spawning area available in Tokyo Creek, recommended escapements are 830 pinks, 54 chum and 20 coho spawning pairs.

Potential Production Summary

Potential production based on the above escapements and an assumed 10% egg-fry survival: 2465 pinks, 267 chum and 113 coho could return to Annette Island.

Figure 27. TOKYO CREEK

Overall Stream Bottom Composition

fork: 10% rubble, 20% cobble, 40% gravel, 10% pebble, 15% sand, 5% silt, trace muck. Some - fair quality gravels.
 Patchy - 70m² above fork and 95m² below Tokyo Creek. **Gravel Compaction**

Spawning Area Available Above High Tide Mark (HTM)

None available.

Intertidal Spawning Area

Rearing Area Small pools are scattered throughout -
 p:r-3-4:1/ in reach near Inn - riffles dominate .4m / to 1.2m

Pool/Riffle Frequency (P:R Ratio) elsewhere. **Ave. Pool Depth/Range** **Ave. Pool Size/Range**

LOD and debris from old Inn provide excellent cover - also, overhanging vegetation and undercut banks.
Available Cover

Sparse - diptera, larvae, ephemeroptera and trichoptera observed, though.

Aquatic Invertebrates/Available Food Source

Very little; however, some algal growth occurs, especially near the Old Inn.

Aquatic Vegetation

Skunk cabbage, ferns, currant and other berries with predominately spruce, hemlock, alder and some cedar.
Terrestrial Vegetation

Intense - 90% above Fork and 90-95% below Tokyo Creek Fork.

Shading

Very little off channel development - so areas with no LOD and a steep gradient are poor rearing habitat

Extent and Quality of Rearing Area

areas, however, areas with abundant LOD (like around the Inn) are good for rearing.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, cutthroat and coho use creek.

Use by Fish

Little to no known fishing pressure (used to be when Inn was operating).

Use by Fishermen

Wildlife Present

None seen, evidence of beaver, mink, and land otter though (11/24/71).

Comments and Recommendations

No habitat improvements recommended; manage creek mainly as a coho nursery area (due to limited spawning area), although pink, chum, and cutthroat do use the creek also.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
1972	Pinks	Adults	380	-	USFWS Escapement Estimate
1973	Pinks	Adults	406	-	USFWS Escapement Estimate
1975	Pinks	Adults	20	-	USFWS Escapement Estimate
1976	Pinks	Adults	2410	-	USFWS Escapement Estimate
6/19/81	Coho	Fry	Over 100	-	Thick near old Inn.

Survey(s) and Dates Conducted

J. Yuska, C. Huntington, 6/19/81 and USFWS, 11/2/71 and 5/24/72

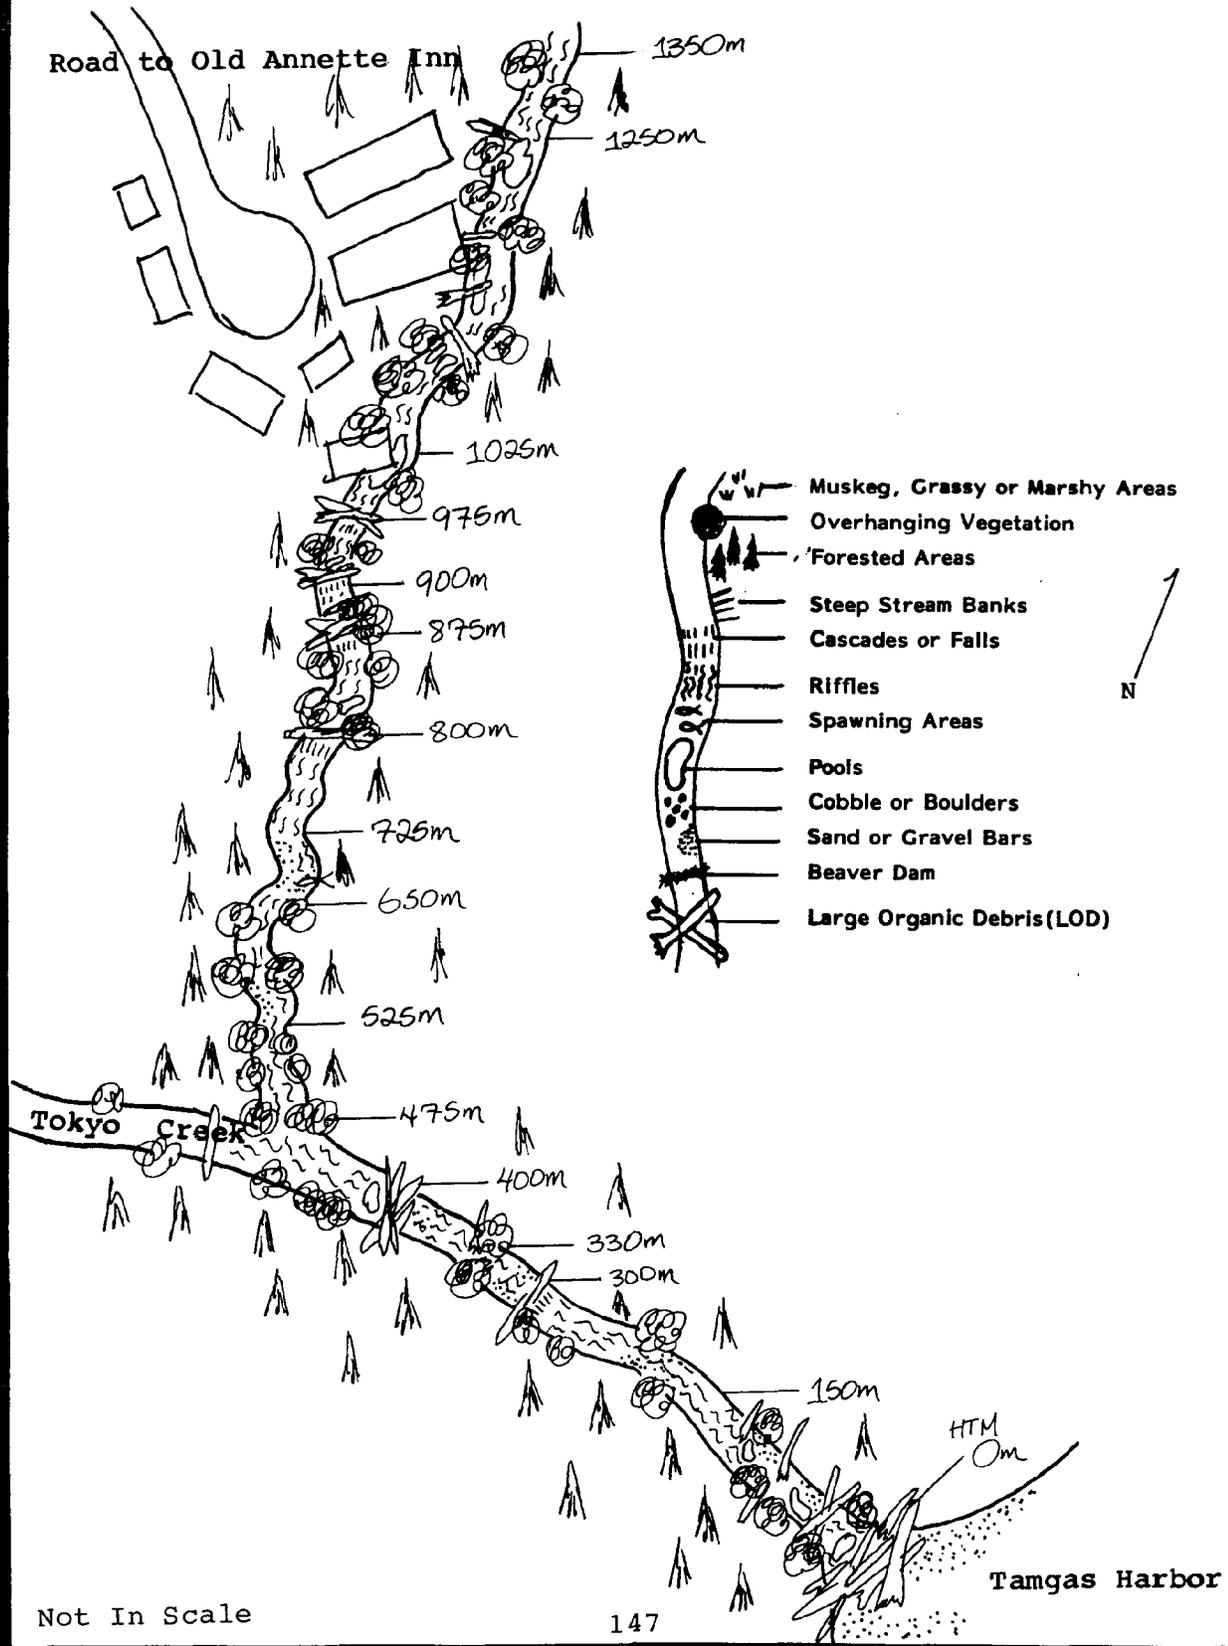

Recommended Escapement

According to spawning area available and rearing area for coho, recommended spawning is 275 pink, 18 chum and 10 coho spawning pairs.

Potential Production Summary

Given the above escapement level and an assumed 10% egg-fry survival rate, potential production from Annette Inn Creek is 817 pinks, 89 chum, and 56 coho.

Figure 28. ANNETTE INN CREEK

Not In Scale

ANNETTE INN CREEK

Watershed No. 405-02
Stat. No. 101-26-001

0m Beach log pile.

0-150m Alot of LOD with a few large pools and fair rearing area.

300m .3m falls over log.

330m Creek runs under roots and muskeg.

400m LOD (4 logs piled up).

150-475m Fairly swift flow of predominantly riffles and runs with marginal coho rearing habitat (another "muskeg land bridge" where creek flows under roots and muskeg). Tokyo Creek comes in at 475m.

525m Lots of deep, slow runs with undercut banks with depth to .7m.

650m Banks are undercut, consisting of muskeg and root tangles with some rock.

725-790m Runs and riffles.

800m LOD influence increases here, .5m high passable debris jam.

875m Passable debris jam.

900m Passable debris jam.

975m Passable debris jam with .4m falls.

1025m Lower end of debris jam from abandoned Inn.

1025-1250m Alot of rearing area here due to debris jams from old Inn that ends at 1250m.

1350m Very little spawning area here or above, with some rearing area, no barriers to here. Channel hard to follow and splits into muskeg and heavy muskeg forest understory.

Spawning Area:

No intertidal spawning area.

Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity Muskeg water.	Color	D.O.	CO₂
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

Mainly mud, sand, and organic matter (twigs, branches, bark and leaves).
Overall Stream Bottom Composition
 Alot of fines.
 Gravel Compaction
 Hard to see where coho spawn - less than 1% area is available; only 2 or 3 spawning areas exist
Spawning Area Available Above High Tide Mark (HTM)
 with room for 1 or 2 redds (coho may be spawning in Moss Pt. Creek and excess fry migrating over to this creek).
 None - intertidal area heavily clogged with logs.

Intertidal Spawning Area

Rearing Area Mostly pools - p:r = 10:1 - poorly defined, shallow (.05m) riffles. .15m / to .40m Small / --
Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range
 Alot of undercut banks, LOD and pools - extensive cover under heavy vegetation also.
Available Cover
 Scarce - diversity low / terrestrial food sources.
Aquatic Invertebrates/Available Food Source
 Very little primary productivity.
Aquatic Vegetation
 Tight and dense - salt tolerant sedges, Cinquefoil, skunk cabbage, alder, trees are cedar, hemlock and spruce.
Terrestrial Vegetation
 Dense - 90%.
Shading
 Whole creek is rearing area - limited only by small creek size.
Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Probably utilized by coho only if utilized at all.
Use by Fish
 No known fishing.
Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Coho only, probably utilize creek - the fry present may be excess fry (pushed out of Moss Pt. Creek by competition for space) that immigrated over to Moss Cove Creek and that were not yet smolts.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/3/81	Coho	Fry	Over 20		

Survey(s) and Dates Conducted

C. Huntington, E. Biggs, and J. Yuska, 6/3/81

Recommended Escapement

Only coho seem to utilize this creek and there is space for only 1 or 2 redds, therefore, escapement recommended is 2 coho spawning pairs.

Potential Production Summary

11 coho could return to Annette Island if 2 spawning pairs were successful.

Spawning Area Available Above High Tide Mark (HTM)
spawnable with fair to good quality gravels = 1575m² fair quality area.

None
Intertidal Spawning Area

Rearing Area Most pools are small pockets behind snags and LOD, a few large pools and beaver ponds.
p:r = 1:4 .35m to 1.5m above runway 6 x 12m / --
Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range

Relatively abundant provided by deep undercut banks, beaver pond, root wads, overhanging vegetation and LOD.

Available Cover
Sparse near runway - below runway organic matter on creek bottom is good for chironomid larvae, (they are present).

Aquatic Invertebrates/Available Food Source
Sparse - some algae on rocks.

Aquatic Vegetation
Thick and tight riparian vegetation of mainly alder and berries; canopy is spruce, hemlock and cedar.

Terrestrial Vegetation
Intense below 1500m - 90%, open above 1500m - 10% due to topography only.

Shading
Some excellent physical rearing habitat exists especially around runways and in beaver ponds below

Extent and Quality of Rearing Area
the dirt airstrip.

Reported and Suspected Use of Stream by Fish and Fishermen
Pink, chum, coho, and cutthroat utilize creek extensively; rainbow have been caught in lake.

Use by Fish
Heavy subsistence use occurs, as well as intense sport fishing (not limiting), around the airstrips.

Use by Fishermen

Wildlife Present
Heavy beaver use and land otter have been spotted.

Comments and Recommendations No habitat improvements recommended.
Moss Point Creek is a major salmon producing creek on Annette Island. A lot of fair quality spawning area and rearing area is available. Beaver dam at 1625m with a 1.25 ft drop may be a barrier to pink and chum, but they would not utilize the creek above this point anyway. Entire creek section is used by salmonids. Escapement counts are recommended on an annual basis.

9/17/81	Pinks	Adult	1083	4	Foot count - peak count 1981.

Survey(s) and Dates Conducted

E. Biggs, J. Yuska, C. Huntington, 6/4/81 and USFWS, 11/24/71, 5/2/72, 7/23/75 plus escapement counts.

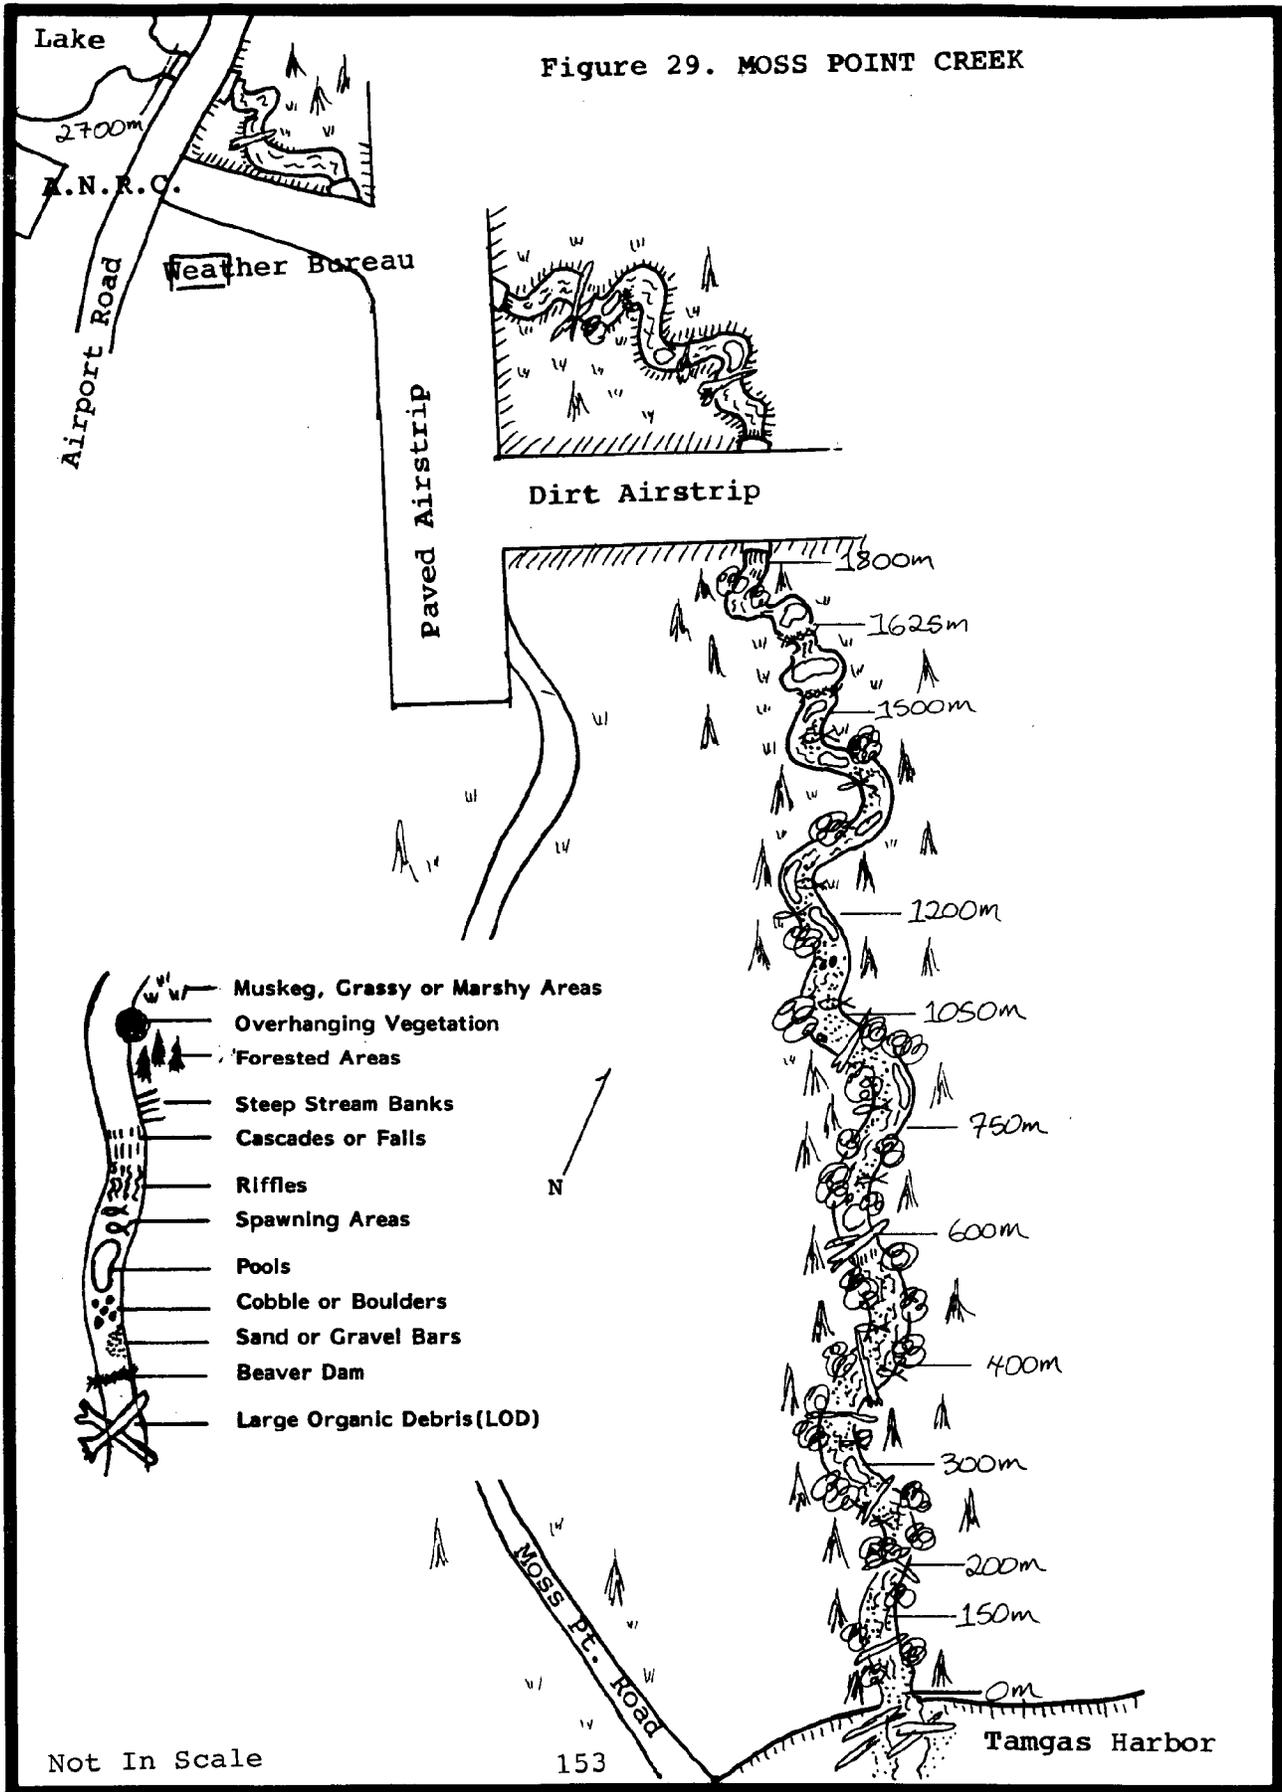

Recommended Escapement

2625 pinks, 100 chum and 45 coho spawning pairs could utilize this creek successfully.

Potential Production Summary

Potential production resulting from this creek given the escapement above could be: 7796 pinks, 495 chum and 254 coho returning to Annette Island assuming a 10% egg-fry survival rate.

Figure 29. MOSS POINT CREEK

Not In Scale

Tangas Harbor

MOSS POINT CREEK

Watershed No. 405-04
Stat. No. 101-26-003

- 0-150m Creek mouth at 0m, High Tide Mark (HTM), Average Stream Width (ASW) = 4m, Average Stream Depth (ASD) = .10m; creek is a riffle/glide with spawning area beginning at 50m.
- 150-200m ASW = 2-3m, ASD = .35-.40m - gravels are angular and coarse. At 200m, canopy increases to 70% with good rearing area and alot of undercuts.
- 200-300m Alot of fines mixed in with the gravels; there is a pool at 300m that is 10-12m long, 5m wide and .05m deep.
- 300-400m Good spawning areas here, but gravels are angular.
- 400-600m Still is some good spawning areas; at 600m there is a 2 ft drop over LOD with pool built up behind logs.
- 750m 4.0 cm 0+ (age - less than a year old) trout seen.
- 1050m Canopy opens up a little and bottom material increases in size.
- 1200m Wide pools with shallow, undercut banks - spawning material is of best quality since 0m, but still not excellent.
- 1500m Stream opens up into muskeg, grasses and ponds. 35% spawning area from 0-1500m.
- 1625m Beaver dam with a 1.25 ft drop.
- 1625-1800m ASW = 1m, creek flows out of passable culvert under dirt airstrip.
- 1800+m Creek above dirt strip flows out of a passable culvert under the paved airstrip: ASW = 1.5m, ASD = .5m (deep), the flow is slow with alot of organic matter and fines in the sediment (no spawning areas); excellent rearing habitat with pools to 1.5m, steep banks with undercut banks and overhanging grasses and shrubs, and some "blown-out" abandoned beaver dams (some LOD in channel, but not abundant).
Above beginning of culvert of paved airstrip, creek flows from a third culvert under the airport and through a section similar to the section described above.
- 2700m At .5m above third culvert, is a lake situated next to the old B.O.Q. building (which is the Annette Natural Resource Center), a screen over the culvert mouth is broken, but may partially block adult fish passage. Coho jacks (precocious male salmon) and trout caught in lake.

Spawning Area: No intertidal spawning area.

Above HTM, 0-1500m 1575m² spawning area of fair quality available.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Spawning Area Available Above High Tide Mark (HTM)
 coho (probably no spawning area is available above the beaver dams), 135m² total areas available.

None

Intertidal Spawning Area

Rearing Area

Most of the stream is riffles, runs, and glides - pools occur in bends and behind beaver dams. .20m/ to .45m Relatively small / --
Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range
 Abundant cover is provided by undercut banks, root tangles, pools and ponds, and overhanging vegetation.
Available Cover
 Scarce - some caddisflies, mayflies and diptera observed however.
Aquatic Invertebrates/Available Food Source
 Some moss and algae occurs on the rocks.
Aquatic Vegetation
 Skunk cabbage, ferns, currant, salmonberry and alder - canopy is hemlock and spruce.
Terrestrial Vegetation
 98% due to riparian vegetation and canopy, decreases to 75% above 175m, mainly due to riparian vegetation.
 Shading
 A moderate amount is available - coho probably do not utilize the beaver ponds because no spawning
Extent and Quality of Rearing Area
 occurs behind them and fry cannot traverse dams. However, habitat is fair below dams, but it lacks large deep pools.

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks and coho mainly use creek, although chum probably utilize it also.
Use by Fish
 No fishing known.
Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

This stream is small, but does produce some salmon - escapement count in 1981 is impressive.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/21/81	Coho	Fry	6	-	
9/1/81	Pinks (mixed)	Adults	1200	-	Ball counted outside mouth (aerial count) - peak count, 1981.

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, 6/21/81 and USFWS, 7/10/75

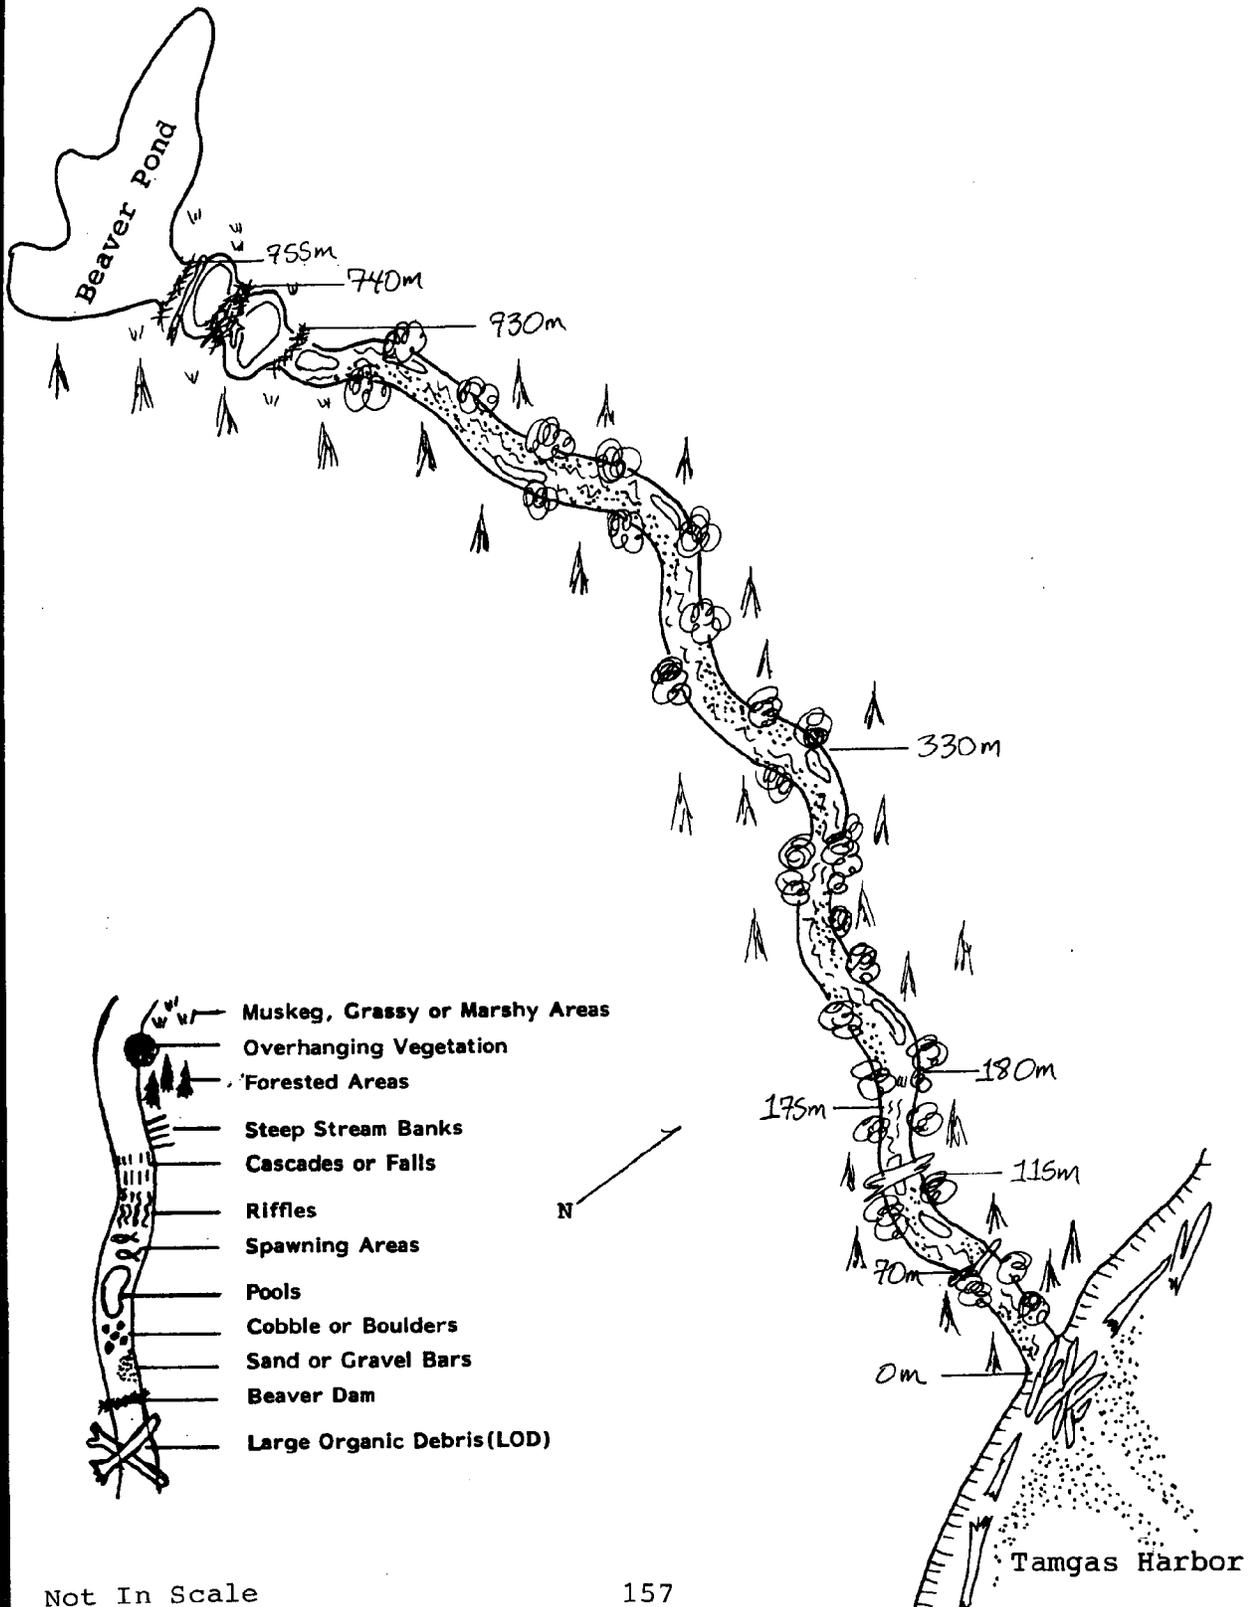

Recommended Escapement

225 pinks, 15 chum and 4 coho spawning pairs could probably utilize this creek.

Potential Production Summary

Due to the number of fines in the gravel, a 1.2% egg-fry survival rate will be assumed. Given the above escapement, production potential is estimated at 90 pinks, 10 chum and 3 coho returning to Annette Island.

Figure 30. DEER CREEK

Spawning Area

50% gravels, 18% pebble, 17% sand, 10% silt, 5% cobble.

Overall Stream Bottom Composition

Somewhat angular gravels with a lot of fines mixed in.

Gravel (granitic) is small with some fines, but is okay for pinks, 25m² is available (includes gravel compaction)

Spawning Area Available Above High Tide Mark (HTM)
intertidal area) - okay for a few pinks although chum and coho could use also.

See above.

Intertidal Spawning Area

Rearing Area

Pools small

Pool/Riffle Frequency (P:R Ratio)	--	Ave. Pool Depth/Range	--	Ave. Pool Size/Range	--
--	----	------------------------------	----	-----------------------------	----

A lot of LOD covers creek, along with root wads, provide a moderate amount of cover.

Available Cover
Sparse - predominately caddisfly and diptera larvae.

Aquatic Invertebrates/Available Food Source
Some non-filamentous algae on rocks.

Aquatic Vegetation
Currant, other berries and shrubs, and alder create a very thick riparian vegetation margin. Forest is hemlock and spruce.

Terrestrial Vegetation
99% due to riparian vegetation, canopy and topography (high banks).

Shading
Coho do utilize the creek.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks, coho, and probably chum utilize the creek.

Use by Fish
No known fishing occurs.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

A small creek producing small numbers of salmon. No habitat improvements recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/21/81	Coho	Fry	4	--	Seen in lower 30m of creek.
9/1/81	Pinks (mixed)	Adult	About 200	--	In a ball outside creek mouth (aerial count).

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, 6/21/81

Recommended Escapement

Since the available spawning area is intertidal, only pinks and chum probably utilize this creek. Recommended escapement is 42 pink and 1 chum spawning pairs.

Potential Production Summary

Gravels are of marginal quality, so a 1.2% egg-fry survival rate is assumed. Potential production is estimated at 15 pinks and 1 chum.

17.1ppm (8/24/71)	--	63.5ppm (8/24/71)	Little flooding occurs.	
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall	

Spawning Area

Spawning gravel is present throughout stream with a small amount of fines. Old redds were observed

Overall Stream Bottom Composition

and alot more spawning area is available than in Colby Creek. Good quality - a little bit of fines.
Gravel Compaction

83m² is available, which is quite a bit for this small creek.

Spawning Area Available Above High Tide Mark (ifM)

30m² available of marginal quality gravels.

Intertidal Spawning Area

Rearing Area

Several pools occur and one large pool by road (3.6m deep) created by road fill.

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
Abundant due to LOD, overhanging vegetation, beaver ponds and deep pool.	--	--

Available Cover

Relatively abundant - caddisflies and mayflies observed on rocks.

Aquatic Invertebrates/Available Food Source

Alot of filamentous green algae.

Aquatic Vegetation

Thick riparian vegetation mainly composed of berries and alder, canopy is spruce and hemlock.

Terrestrial Vegetation

Intense much of creek stretch - overall 50% (20% due to banks and 30% to vegetation).

Shading

Abundant good rearing habitat is available (many fry spotted); however, it is doubtful that fry get into

Extent and Quality of Rearing Area

origin lake due to high beaver dam.

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks, chum, and coho utilize creek.

Use by Fish

Fishing used to be heavy, but light pressure now (probably) - kids swim in pond in summer.

Use by Fishermen

Wildlife Present

Heavy beaver activity.

Comments and Recommendations

Culverts on Tangas Apt. Road are barriers to salmon at low tide; beaver dam barrier, 1.8m high, occurs

at 520m, preventing adults and fry from entering lake. This stream could produce a significant number of salmon, however, underescapement may be occurring. Escapement counts in the creek are recommended.

Improving culvert for fish movement is recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
1971	Low escapement recorded due to heavy subsistence fishing.				
1972	Low relative abundance of pinks was recorded.				
6/21/81	Coho	Fry	750	-	Very numerous in creek.
9/1/81	Pinks	Adults	300	-	Two balls of fish were seen near mouth; however, 200 in one ball may be returning from hatchery release out culvert near creek culvert.

Survey(s) and Dates Conducted

J. Yuska, 6/21/81 and USFWS, 9/24/71

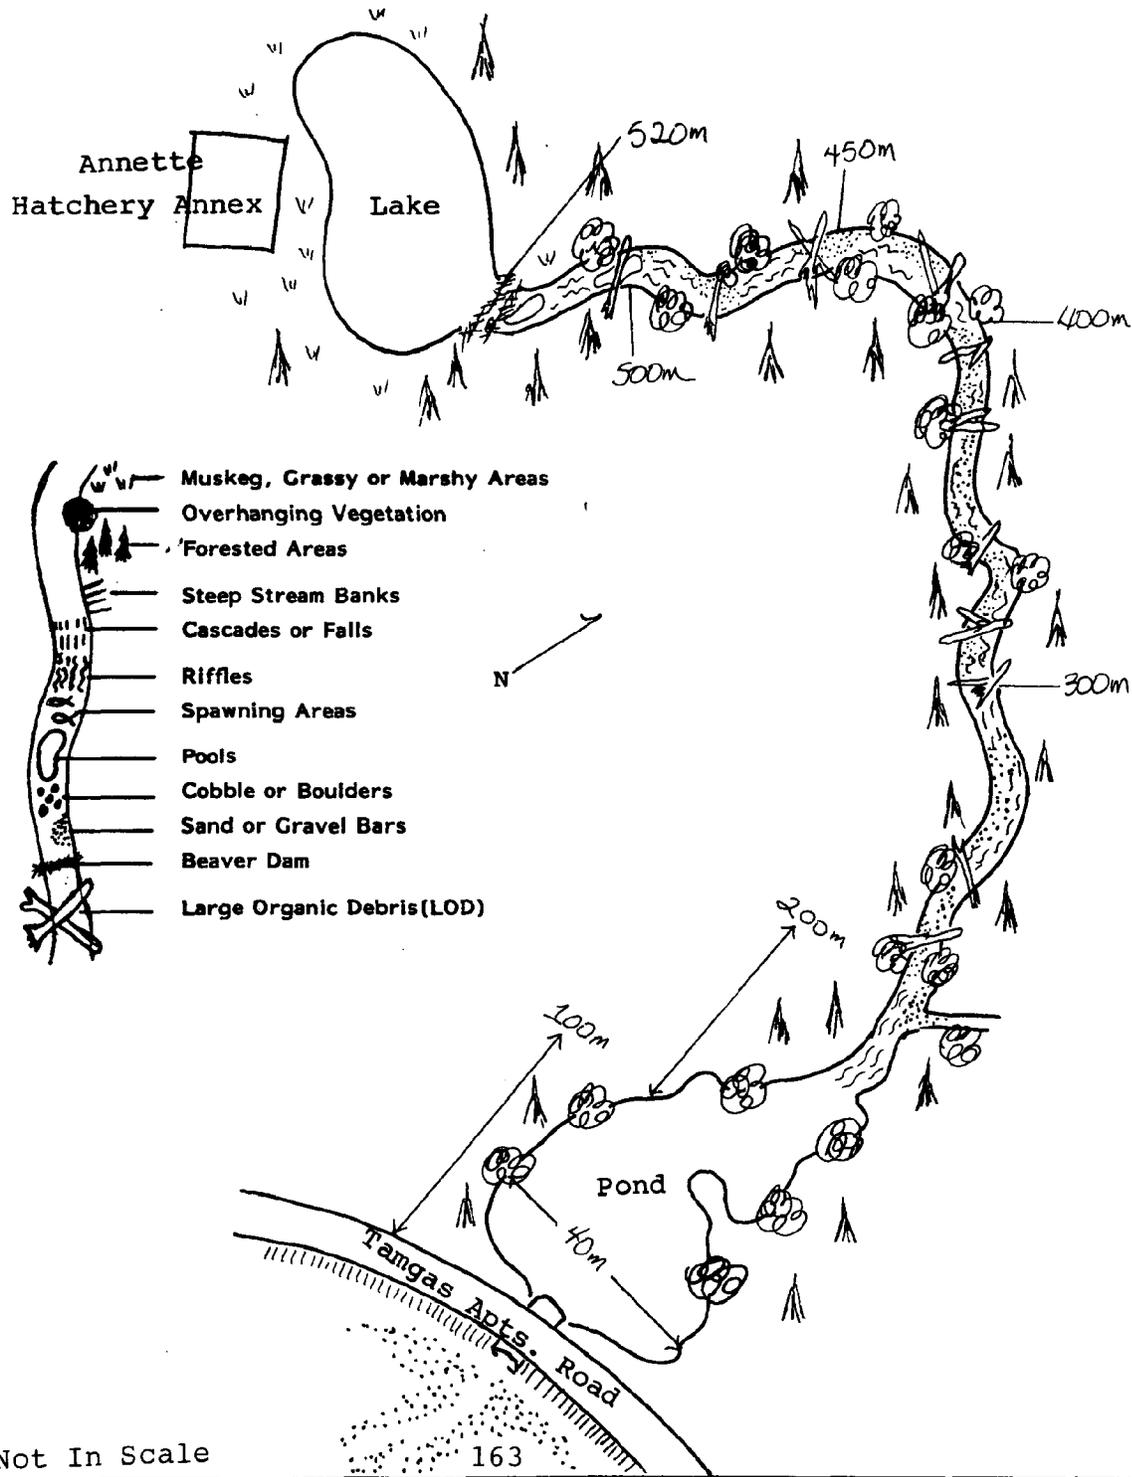

Recommended Escapement

Recommended escapement is 188 pinks, 12 chum and 7 coho spawning pairs based on available spawning area.

Potential Production Summary

Gravel is generally of good quality so a 10% egg-fry survival rate will be assumed. Based on the above escapements, potential production is 560 pinks, 60 chum and 40 coho returning to Annette Island.

Figure 31. COAST GUARD CREEK

Not In Scale

COAST GUARD CREEK

Watershed No. 405-07
Stat. No. 101-26-006

- 50m 12m wide x 50m long intertidal spawning area with 5% gravels (30m² total area available) of marginal quality.
- 0m Upper end of culvert (passable) that goes under the gravel Tamgas Apartment Road. High Tide Mark (HTM) at culvert.
- 0-100m A large pond here 40m wide (used as swimming hole in summer).
- 100-200m Stream narrows from pond to stream. A tributary with .125 cfs flow and 10m² spawning area enters at 200m.
- 200-300m Average Stream Width (ASW) = 1m, Average Stream Depth (ASD) = .07m, with 20% gravels (20m² spawning area); 14 coho fry observed.
- 300-400m ASW = 1.5m; bottom composition: 30% gravels, 30% sand, 40% pebbles (45m² spawning area); 15 coho fry seen and rearing habitat is good in this stretch.
- 400-500m Alot of algae and insects in bottom with alot of LOD in the stream; canopy shading 50% (20% due to banks and 30% vegetation). At 450m is an old redd and 7.5m² spawning area (only area in stretch).
- 500m 2 coho fry seen in pool.
- 520m Beaver dam behind which is the creek origin, small lake next to the Annette Island Hatchery Annex.

Spawning Area:

Intertidal	30m ²
Above HTM, approximately	83m ²

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Colby Creek Stream	101-26-007 Number	405-08 Geocode
Flows E into Tangas Harbor, .7 mi long. Muskeg pools and run-off. / Forested muskeg flats, .5mi ² in area.		
Location	Origin	Watershed Type

Spawning Area

Overall creek bottom is 80% gravels (mostly small, 2.5-3 inches in diameter), the rest is pebbles, sand, mud, and silt. Gravels "dirty" - moderate compaction. Gravel Compaction

Two probable redds observed - 5% spawning area in section surveyed. Total available area is approximately

Spawning Area Available Above High Tide Mark (HTM)

55m².

Limited - marginal quality gravels.

Intertidal Spawning Area

Rearing Area

p:r = 4:1; riffles are light and average depth = .08m

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
	.20m / to .60m	-- --

Excellent cover provided by tight and thick riparian vegetation, 40-50cm undercut banks, and some LOD.

Available Cover

None seen / Food source is primarily terrestrial insects.

Aquatic Invertebrates/Available Food Source

Scarce

Aquatic Vegetation

Muskeg vegetation; grasses, apple, alder in cedar, hemlock, spruce canopy.

Terrestrial Vegetation

30-50% shading, mainly due to canopy - creek open to just above HTM.

Shading

Alot of rearing area is available in small pools, under LOD and undercut banks.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, and coho utilize the creek.

Use by Fish

Some subsistence fishing occurs.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

This creek produces a moderate amount of salmon and is limited by the small creek size and marginal quality of the gravels. More creek area could be opened by placing a culvert in the road; however, it is doubtful that the increase in production realized would justify the cost.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments

Addition Water Quality Data:

7/31/79 - Flow - .01 cfs (questionable), Temp. (Water) - 14.0C, Tannic Acid - 54 mg/l
 8/25/79 - Flow - 12 cfs, 9/26/74 Temp. (Water) - 12.2C, 10/11/74 Temp. (Water) - 13.9C.

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, J. Yuska, 6/3/81 and USFWS, 8/25/71 and Pacific Rim Planners, Inc., 7/31/79

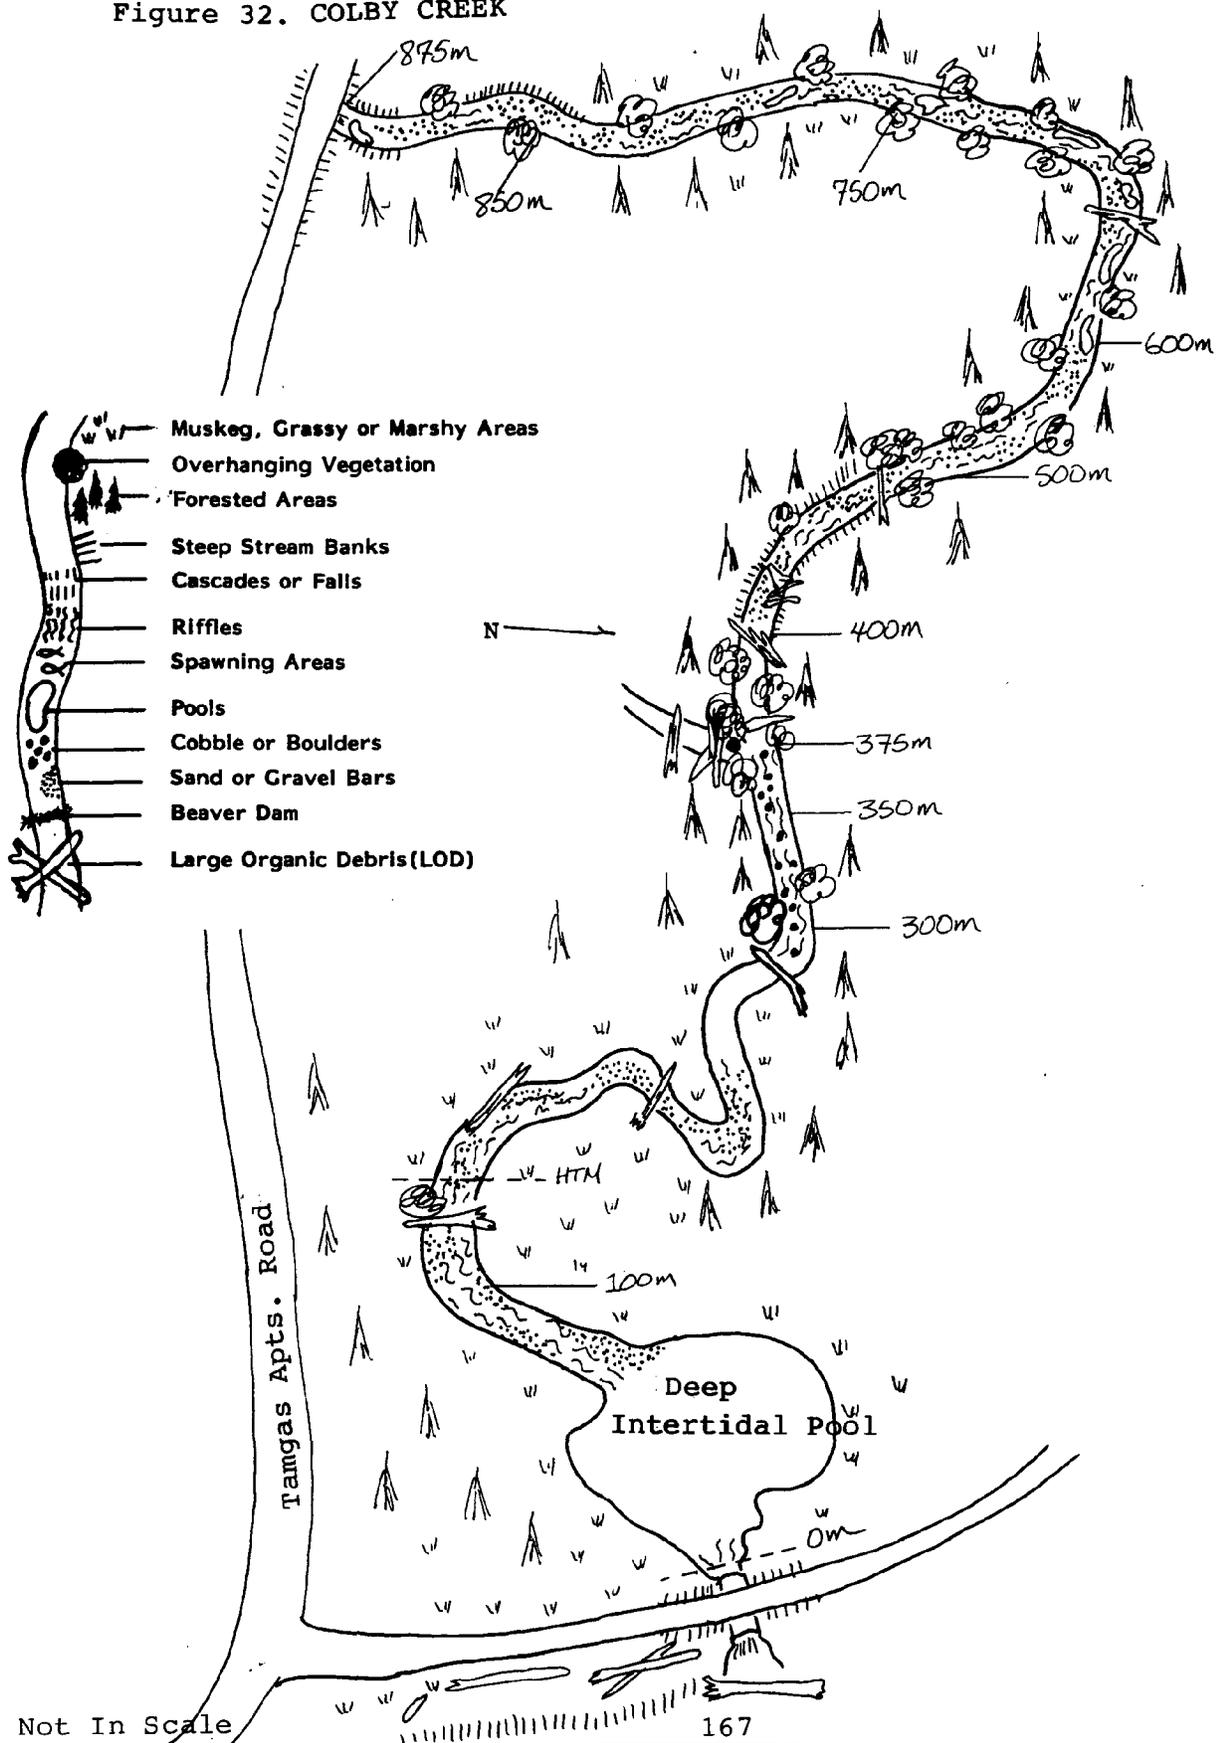

Recommended Escapement

According to available spawning area and historical escapements, recommended escapement is 200 pink, 6 chum, and 5 coho spawning pairs be allowed to spawn in this creek. Historical escapements are higher, this is probably a harvestable surplus from the creek and strays attracted to the creek culvert.

Potential Production Summary

Assuming a 10% egg-fry survival rate (assuming gravels experience a certain amount of fishing and based on previous production), potential production based on the above escapements is: 594 pinks, 30 chum and 28 coho. These figures are lower than realized production during several years exhibiting the conservativeness of the estimate. In those years, marine survival was probably much higher than 2%.

Figure 32. COLBY CREEK

Not In Scale

COLBY CREEK

Watershed No. 405-08
Stat. No. 101-26-007

0m Upper end of culvert (passable) flowing under small dirt road. Above 0m is a large, deep intertidal pool.

100m Adverage Stream Depth (ASD) = .30m, banks are undercut to .4-5m, gravels "dirty" mixed with alot of fines.

150m High Tide Mark (HTM) above a large log across the channel.

300m Gradient increases and canopy increases to 30% cover, bottom has cobble, gravel and angular boulders. Below 300m, creek flows through a grassy meadow.

350m ASW = 1.7m

375m Stream forks under dense LOD.

400m Stream still choked with LOD, riparian vegetation is very thick and stream velocity is moderate to fairly high.

500m Low canopy, LOD chokes heavily undercut banks; stream gradient moderate to high with cutthroat and coho fry observed here and above.

600m Gradient low, better quality pools and rearing area here; many fry spotted.

750m Canopy 30-50%, gravels are ½ inch with alot of fines mixed in; undercut banks.

850m Old redds observed.

875m Rock barrier at Tamgas Apartment Road (no culvert). From 600m, trees are stunted as area is generally muskeg.

Spawning Area: Limited, Above HTM only about 55m² of patchy spawning area is available.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Total Alkalinity	Total Hardness	Dissolved Solids
		Other/Overall

Spawning Area

Large rubble/boulder (of less than 12 inch size) predominates bottom with angular gravels mixed in.

Overall Stream Bottom Composition

Alot of organic floc occurs in the upper gravels and they are angular.

Gravel Compaction

Limited; little spawning area is available for coho and steelhead (gravels are small -1.5 inch diameter Spawning Area Available Above High Tide Mark (HTM) size predominating). Much more occurs in the lower end. Only about 50m² occurs above HTM.

Some available, but it is limited - actually the best gravels occur intertidally, approximately 250m² is Intertidal Spawning Area available.

Rearing Area

p:r = 4:1, pools are located evently throughout stream as well as the four riffles./ .30m / to .70m 3m diameter / --

Pool/Riffle Frequency (P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Limited except in lake area.

Available Cover

Sparse - however, diptera and trichoptera were observed.

Aquatic Invertebrates/Available Food Source

Sparse - the thickest occur next to the lake where moss covers 10% of the bottom.

Aquatic Vegetation

A tight canopy occurs near the mouth of alder, sitka, spruce, and hemlock mainly.

Terrestrial Vegetation

60-90% due to canopy in lower end of creek; it opens up near lake.

Shading

Extensive, good quality rearing occurs in the lake, however, it is limited in the stream itself.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, and coho utilized the creek.

Use by Fish

Some subsistence fishing occurs.

Use by Fishermen

Wildlife Present

Beaver activity at Hospital Lake; some land otter predation reported in 1971.

Comments and Recommendations

USFWS removed a log barrier, 165m up the creek on 9/15/71. At 300m, another large log that may be a barrier should also be removed. There may be additional, unsurveyed spawning area above the lake to allow so many spawning fish in the creek, because only a couple redd sites occur suitable for coho. This creek is mainly a pink and chum producing stream with much of the spawning occurring intertidally.

CONTINUED ON SECOND SHEET

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, J. Yuska, 6/13/81 and USFWS, 8/25/71 and Pacific Rim Planners, Inc., 7-9/79

Recommended Escapement

In 1975, USFWS concluded that spawning area was available for approximately 3200 fish (mainly pinks). According to the spawning area available and historical escapements, recommended escapements are 500 pink, 33 chum, and 5 coho spawning pairs.

Potential Production Summary

Assuming a 10% egg-fry survival because of fair gravel quality and the previous production record, potential production estimates are 1500 pink, 164 chum and 28 coho returning to Annette Island. As with Colby Creek, it can be seen that in many years, this potential is exceeded and shows how conservative the estimate is. Marine survival probably exceeded 2% in those years.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/7/80	Pinks (mainly - mixed)	Adult	3800	--	Ball of fish at mouth (aerial count).
6/3/81	No fish seen				
9/1/81	Pinks (mainly - mixed)	Adult	100-200	--	Ball of fish at mouth (aerial count).

HOSPITAL CREEK

Watershed No. 405-09
 Stat. No. 101-26-008

0m Stream mouth.

75m High Tide Mark (HTM).

150m Passable debris jam, Average Stream Width (ASW) = 5m, Average Stream Depth (ASD) = .1m, canopy is fairly dense.

175m Stream Survey Station, velocity is 1.5 fps.

300m 1m high log across creek (a possible barrier) with a pool .5m deep, 3m wide; canopy shading 60% here.

400m 2 x 20 feet debris dam - probably an old beaver dam, with good spawning area to 450m.

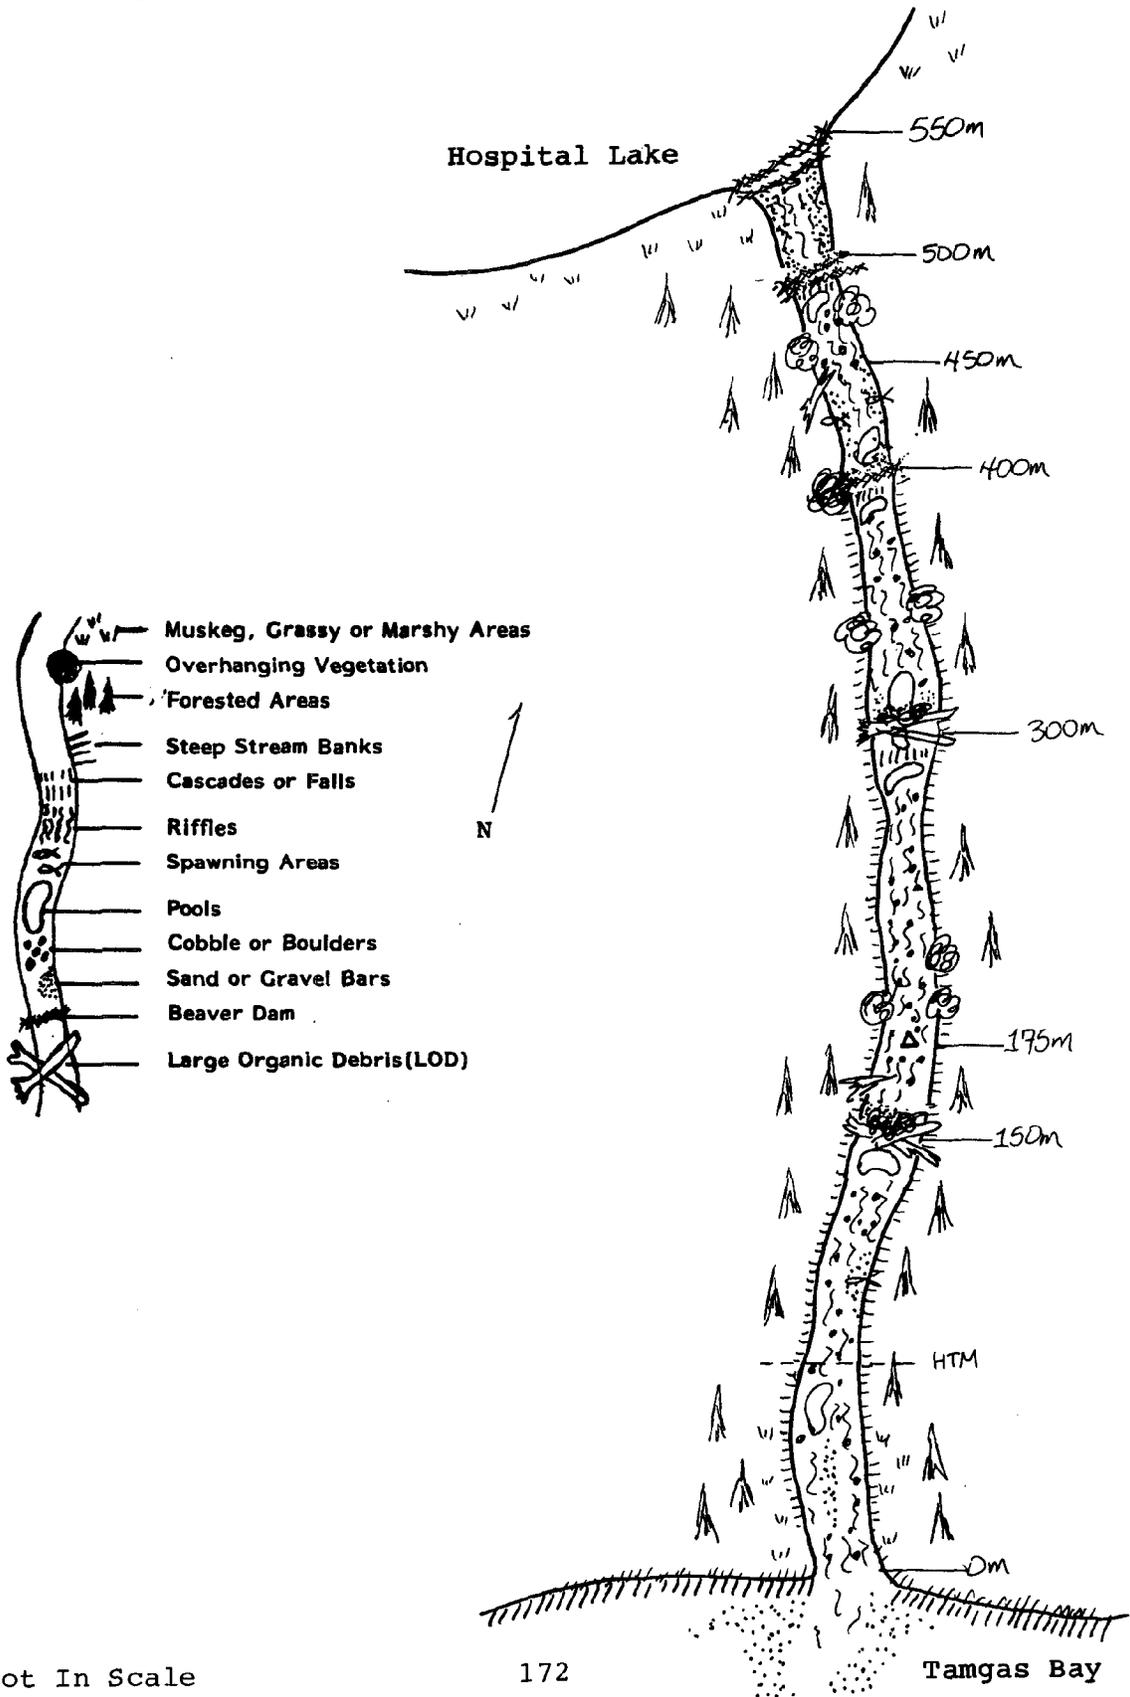

450m Cobble and large boulder substrate begins here.

500m Beaver dam; 10% of bottom covered with moss.

550m Lake and beaver dam; from 500m, some good gravels and spawning area exists. Lake is good rearing habitat.

Spawning Area: Limited, only about 50m² above HTM.

Figure 33. HOSPITAL CREEK

Not In Scale

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Powerhouse Creek I	101-26-015	404-01
Stream	Number	Geocode
Flows S into Tangas Harbor, 1.0 mi long./ Muskeg ponds, springs, and run-off./ Muskeg flats and some mountain foothills.		
Location	900m above High Tide	Origin Above 400m, steepness
6/7/81	Mark (HTM)	may be velocity barrier.
Date Surveyed	Section Surveyed	Barriers
Variable:		Rapid in
1.5-6%	1 cfs to 3 cfs (9/14/71)	1 fps/ upper section.
Ave. Gradient	Flow / Range	Ave. Velocity/Range
Sloped rock and vegetation in soils banks.		
Fairly stable with a little active bank cutting.		Two - small ones.
Streambank Composition	/ Stability	Tributaries

Water Quality

Water quality taken 9/14/71 -	12.8C	10.5C	6.0	Clear / None	Brown	-	36ppm
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO ₂
17.1ppm	12.0ppm	10.4ppm	CaCO ₃	--			
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

15% boulder, 20% rubble, 25% cobble, 15% gravel, 15% pebble, 10% sand - trace silt and organic matter.

Overall Stream Bottom Composition

Good quality - granitic gravels are rounded - minimal.
Gravel Compaction

Only about 1.5% area is available - approximately 20m² area total.
Spawning Area Available Above High Tide Mark (HTM)

40m² good quality area occurs just above the culvert under the B.I.A. road.
Intertidal Spawning Area

Rearing Area Generally pools are shallow, caused by LOD, pools in 30% of bottom, riffles in 10%.

.20m to .30m

-- --

Pool/Riffle Frequency (P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Pools do not provide alot of cover and banks are steep; however, root tangles provide a bit.

Available Cover

A few observed - not dense - diptera, trichoptera and ephemeroptera observed.

Aquatic Invertebrates/Available Food Source

Scarce - there is a little algal growth on submerged rocks.

Aquatic Vegetation

Mosses and ferns, alot of currant, salmonberry, under a hemlock, cedar and spruce canopy.

Terrestrial Vegetation

Intense - 95% due to both thick riparian vegetation and steep banks (topographical).

Shading

Some coho rearing areas are available in the lower end of the creek - but it is not extensive - steep

Extent and Quality of Rearing Area

gradient and sparse cover limits the rearing area available.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum and coho utilize the creek.

Use by Fish

Some reported subsistence fishing occurs.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Spawning area is limited, but of good quality, management of stream should be geared toward pink and

chum, due to limited rearing area available for coho, although they do utilize the creek. The powerhouse tailwaters may attract more pinks than can utilize this creek, creating an overescapement. No

habitat improvement is recommended at this time.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/14/71	Pinks	Observed in creek - not counted.			
1973	Pinks	Adults	100		USFWS Estimated Total Escapement
1975	Pinks	Adults	81	--	USFWS Estimated Total Escapement
1976	Pinks	Adults	42	--	USFWS Estimated Total Escapement
9/7/80	Pinks mainly (mixed)	Adult	1000	--	Seen at creek mouth, an additional were attracted to the power-house tailwaters.
6/7/81	Coho	0+ Fry	3	--	Intertidally (above culvert) and 1 at 150m.
9/1/81	Pinks mainly (mixed)		300-400	-	A ball of fish was outside mouth, some of which may have been attracted by the tailwaters (aerial count).

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, J. Yuska, 6/7/81 and USEFS, 9/14/71

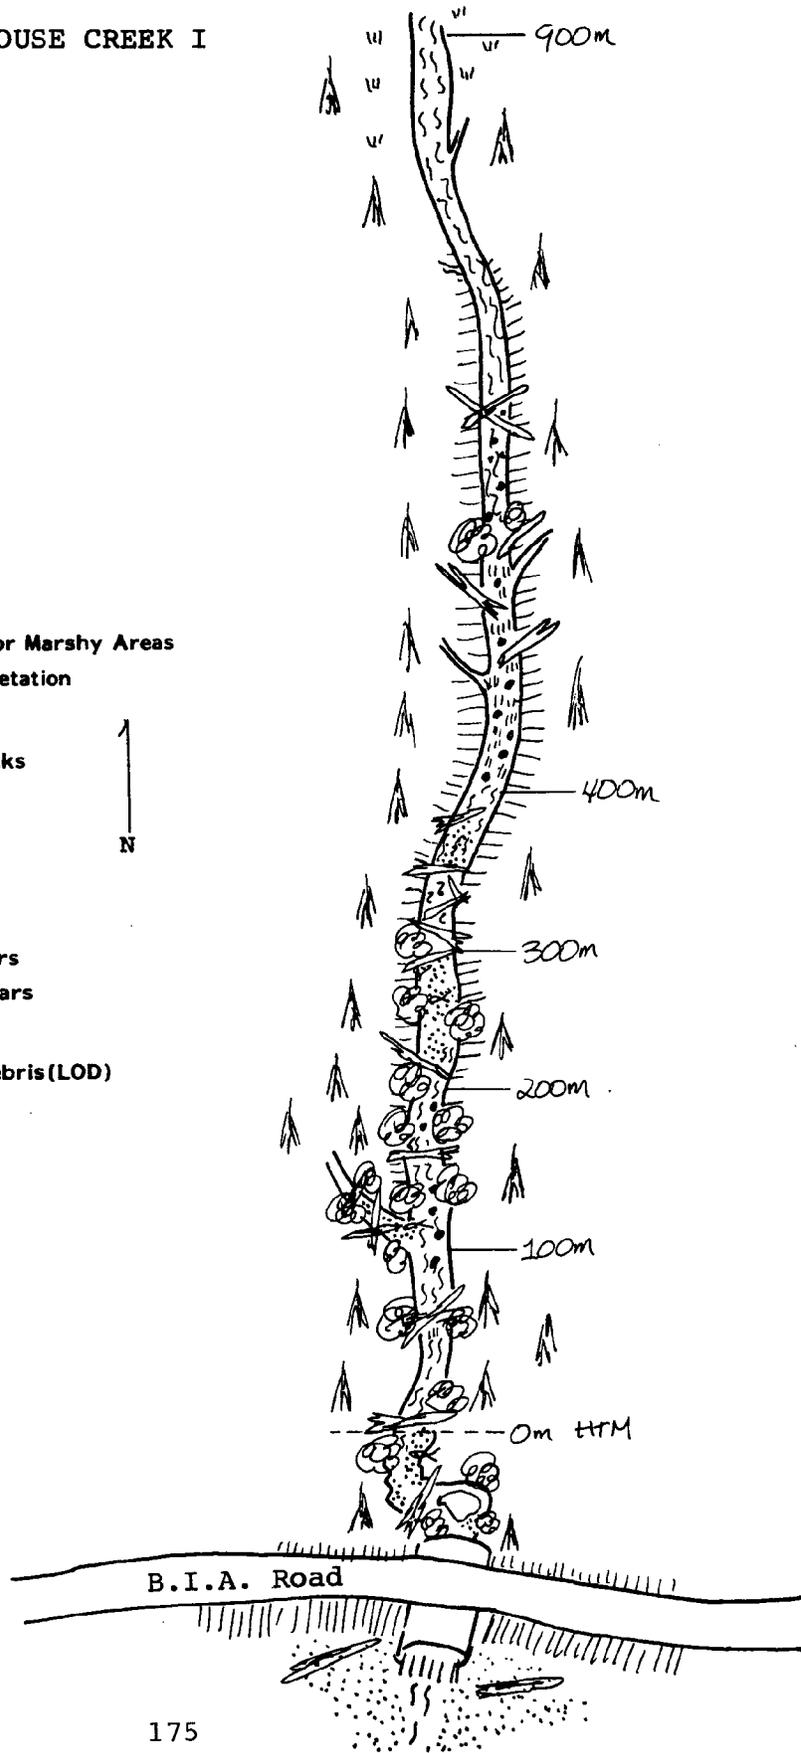

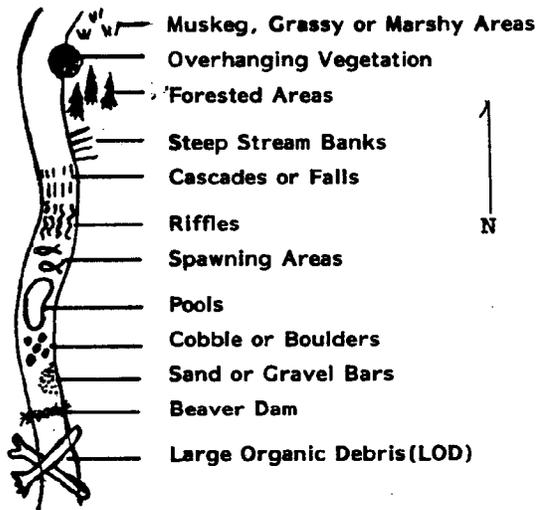

Recommended Escapement

According to available spawning area, recommended escapements are 90 pink, 6 chum and 2 coho spawning pairs (even though historical escapement counts are higher).

Potential Production Summary

Potential production, assuming a 10% egg-fry survival rate, is estimated at 270 pinks, 30 chum, and 11 coho returning to Annette Island. The powerhouse tailwaters may be attracting an artificially high number of pinks to this creek and/or marine survival may have exceeded 2% in a few years resulting in the large escapement figures in past years.

Figure 34. POWERHOUSE CREEK I

Not In Scale

POWERHOUSE CREEK I

Watershed No. 404-01
Stat. No. 101-26-015

- 0m High Tide Mark (HTM). Below 0m is large pool above culvert (under BIA road) and about 40m² of good quality spawning gravels.
- 100m Moderate gradient, bottom is cobbles mixed in with small gravels (too small for spawning).
- 110m Stream splits, tributary has an Average Stream Width (ASW) = 1m, Average Stream Depth (ASD) = 0.5m - spawning areas in tributary could be used during high flows, whole channel is defined by LOD.
- 100-200m (Main Channel)
ASW = .75m, ASD = .08m (more flow and cleaner gravels than in the tributary), large cobble and boulders predominate in the bottom above the tributary, lots of salmonberry on banks of creek.
- 200-300m Better spawning gravels occur, but are still of marginal quality, 80% shading.
- 300-400m Lots of LOD from blowdown (no stumps or logging here). From 110m; banks have gotten steeper.
- 400m At 400m and above, gradient increases; bottom is all cobble and boulder and stream is a sloping cascade (too steep for juvenile salmon migration).
- 900m Stream gets steadily smaller, fed by springs.
- Spawning Area:
Intertidal, 40m² of good quality spawning area.
Above HTM, limited to about 20m² area.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Powerhouse Tailwaters Creek	101-26-016	404-02
Stream	Number Mountain slope	Geocode
Flows W into Tangas Harbor, .12 mi long./ run-off and powerhouse tailwaters. Forested mountain slopes.		
Location	175m from High Tide	Origin
6/11/81	Mark (HTM) to road.	Culvert at B.I.A. Road
Date Surveyed	Section Surveyed	Barriers
Low	.125 cfs / --	sluggish
Ave. Gradient	Flow / Range	Ave. Velocity/Range
Flashy creek - unstable channel.		Stage
Streambank Composition	/ Stability	Moderate
		Flood Height
		.05m / --
		Ave. Width/Range
		Ave. Depth/Range
		None
		Tributaries

Water Quality

--	--	--	--	--	Turbid	--	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO₂	
--	--	--	--	None taken - probably it is okay due to origin.				
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall					

Spawning Area

Mainly fines - mud, sand and organic debris.

Overall Stream Bottom Composition

Heavy - due to fines.

Gravel Compaction

None

Spawning Area Available Above High Tide Mark (HTM)

Of marginal quality, many fines are mixed in, however, 12.5m² area exists.

Intertidal Spawning Area

Rearing Area

3 pools in 175m length.

	2.m	/ --	2 x 3.5m	/--
Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range		Ave. Pool Size/Range	

Alot of LOD occurs due to construction.

Available Cover

None seen.

Aquatic Invertebrates/Available Food Source

Abundant - green filamentous algae covers 50% of the rocks and periphyton occurs on creek bottom.

Aquatic Vegetation

Skunk cabbage, ferns, mosses, salmonberry, and cedar and hemlock.

Terrestrial Vegetation

Up to 50% due to riparian vegetation and canopy.

Shading

Pools and LOD are abundant, but rearing is limited due to small size of creek and flashiness.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Probably pinks only, could use this creek if they use it at all.

Use by Fish

None known.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

The creek itself is of marginal value in salmon production (although before the road was constructed it may have been better), but the tailwaters attract alot of fish.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
------	---------	------	--------------	------	----------

None seen or expected.

Survey(s) and Dates Conducted

J. Yuska, 6/11/81

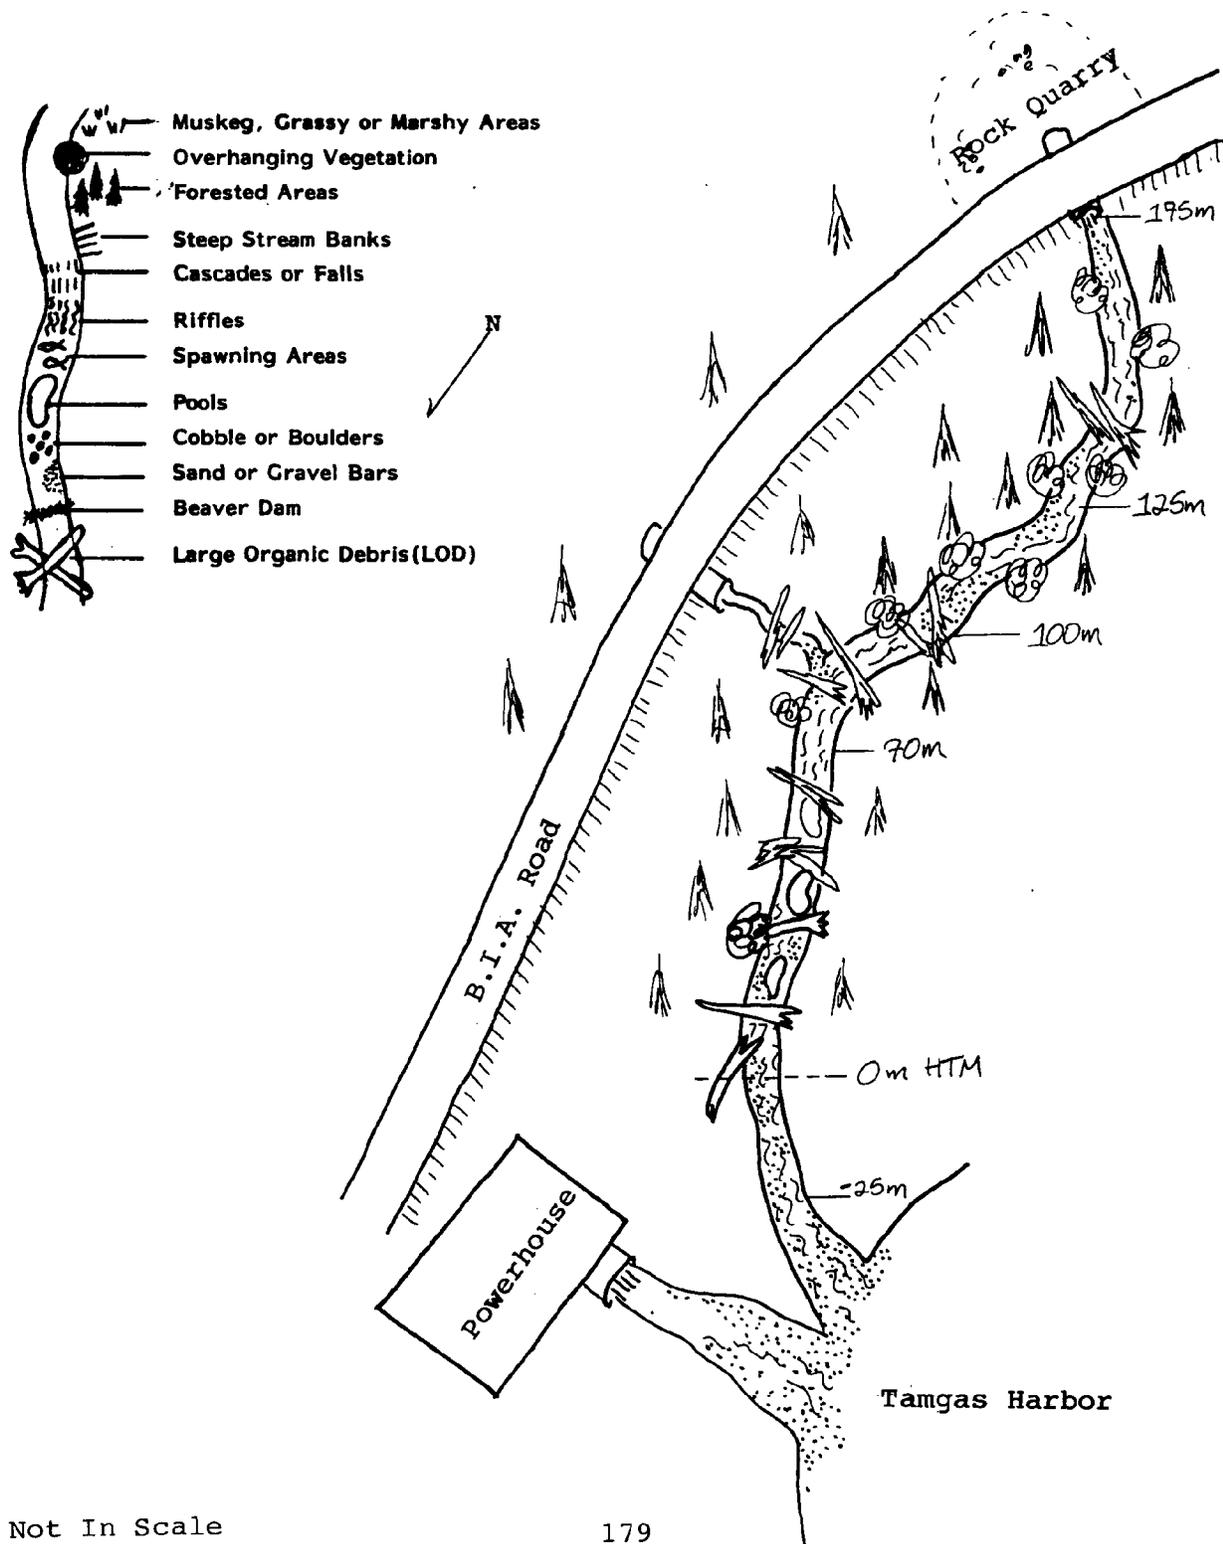

Recommended Escapement

None made.

Potential Production Summary

No production potential is calculated due to the marginal gravel quality and questionable use of the creek by salmon (even though they may be present due to the tailwaters attractive to stray pinks).

Figure 35. POWERHOUSE TAILWATERS CREEK

Not In Scale

POWERHOUSE TAILWATERS CREEK

Watershed No. 404-02
Stat. No. 101-26-016

-25-0m Average Stream Width (ASW) = 2m; bottom composition:
25% usable gravels (marginal intertidal gravels)
30% sand, 45% angular cobble, about 12.5m² spawning
area available. High Tide Mark (HTM) at 0m.

0-70m Three pools in this stretch 2m wide, 3-4m long,
.1-.3m deep; organic detritus abundant with very
fine anaerobic muds area choked with LOD from
road construction.

70-100m ASW = 1m, slow flow over 100% sand.

125-175m 50% canopy shading with alot of periphyton on
the bottom. At 175m, blocked culvert is barrier
to fish (creek flows under the road and comes
immediately from the rock quarry).

Spawning Area:

Limited, intertidal area is about 12.5m²

Above HTM, there is none.

Wildlife Present

--

Comments and Recommendations

Creek not even noticed in 1981 - the creek may have been blocked and partially destroyed and dispersed by the road construction. At one time it had a good sized run. In 1973, USFWS recommends removing log barriers. In 1981, improvements that could be conducted are rebuilding culvert allowing fish passage, and clearing slash and perhaps trenching to encourage channelization. Benefit:cost estimate (based on production) is recommended.

1975	Pinks	Adults	1301	--	USFWS Estimated Total Escapement
1976	Pinks	Adults	524	--	USFWS Estimated Total Escapement

Survey(s) and Dates Conducted

USFWS, 6/12/73

Recommended Escapement

In previous years, this creek may have produced salmon, however, no escapement recommendations can be made since no spawning area was measured.

Potential Production Summary

This creek may have been damaged and its production potential lessened by the construction of the B.I.A. road (it does seem to have been a moderate producer of pink and chum salmon in previous years). No potential production can be estimated without additional surveys and escapement counts.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Trail Creek		101-26-018		403-01	
Stream		Number		Geocode	
Flows SW into Tamgas Harbor, 1.0 mi long.			Mountain slope run-off.		Timbered mountain slope.
Location	350m from mouth to	Origin	Culvert at times and	Watershed Type	
6/11/81	20m falls		20m barrier falls.	Moderate	--
Date Surveyed	Section Surveyed	Barriers		Stage	Flood Height
Low-moderate	2 cfs / --	Rapid / --		1.75m / --	.1m / --
Ave. Gradient	Flow / Range	Ave. Velocity/Range		Ave. Width/Range	Ave. Depth/Range
Flashy creek with unstable banks - alot of bedload transfer occurs during storms - heavy LOD influence.			None		
Streambank Composition / Stability			Tributaries		

Water Quality

--	--	--	--	Clear / None	Clear	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO ₂
--	--	--	--	Turbidity probably occurs during storms.			
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

Cobble and gravels mainly - gravel bars 5-15m wide in areas. Porous gravels swallows flow entirely at

Overall Stream Bottom Composition

times. Some occurs- most gravel is okay.

Gravel Compaction

25% usable gravels occur, but low egg survival is expected due to stream flashiness - 80m² area total

Spawning Area Available Above High Tide Mark (HTM)

occurs below culvert.

120m² area available of marginal quality area - channel is indefinite.

Intertidal Spawning Area

Rearing Area

	Ave. Pool Depth/Range		Ave. Pool Size/Range	

LOD and the pools - a moderate amount available.

Available Cover

Unknown

Aquatic Invertebrates/Available Food Source

Unknown

Aquatic Vegetation

Berries, ferns, moss and timber.

Terrestrial Vegetation

Intense

Shading

Limited due to the flashiness of creek and swift velocity, creek channel disappears entirely during

Extent and Quality of Rearing Area

low flows.

Reported and Suspected Use of Stream by Fish and Fishermen

Only pinks and chum could use the creek.

Use by Fish

None known.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

LOD and slash from road construction influences channel heavily and road culvert is a probable fish fish barrier during low flows. This stream dries up completely at times, and is of minor importance at present in terms of production. Gravels are a bit large for spawning, but usable. This creek would make a good interpretive and scenic trail upstream of road because of falls.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
None seen					

Survey(s) and Dates Conducted

J. Yuska, 6/11/81

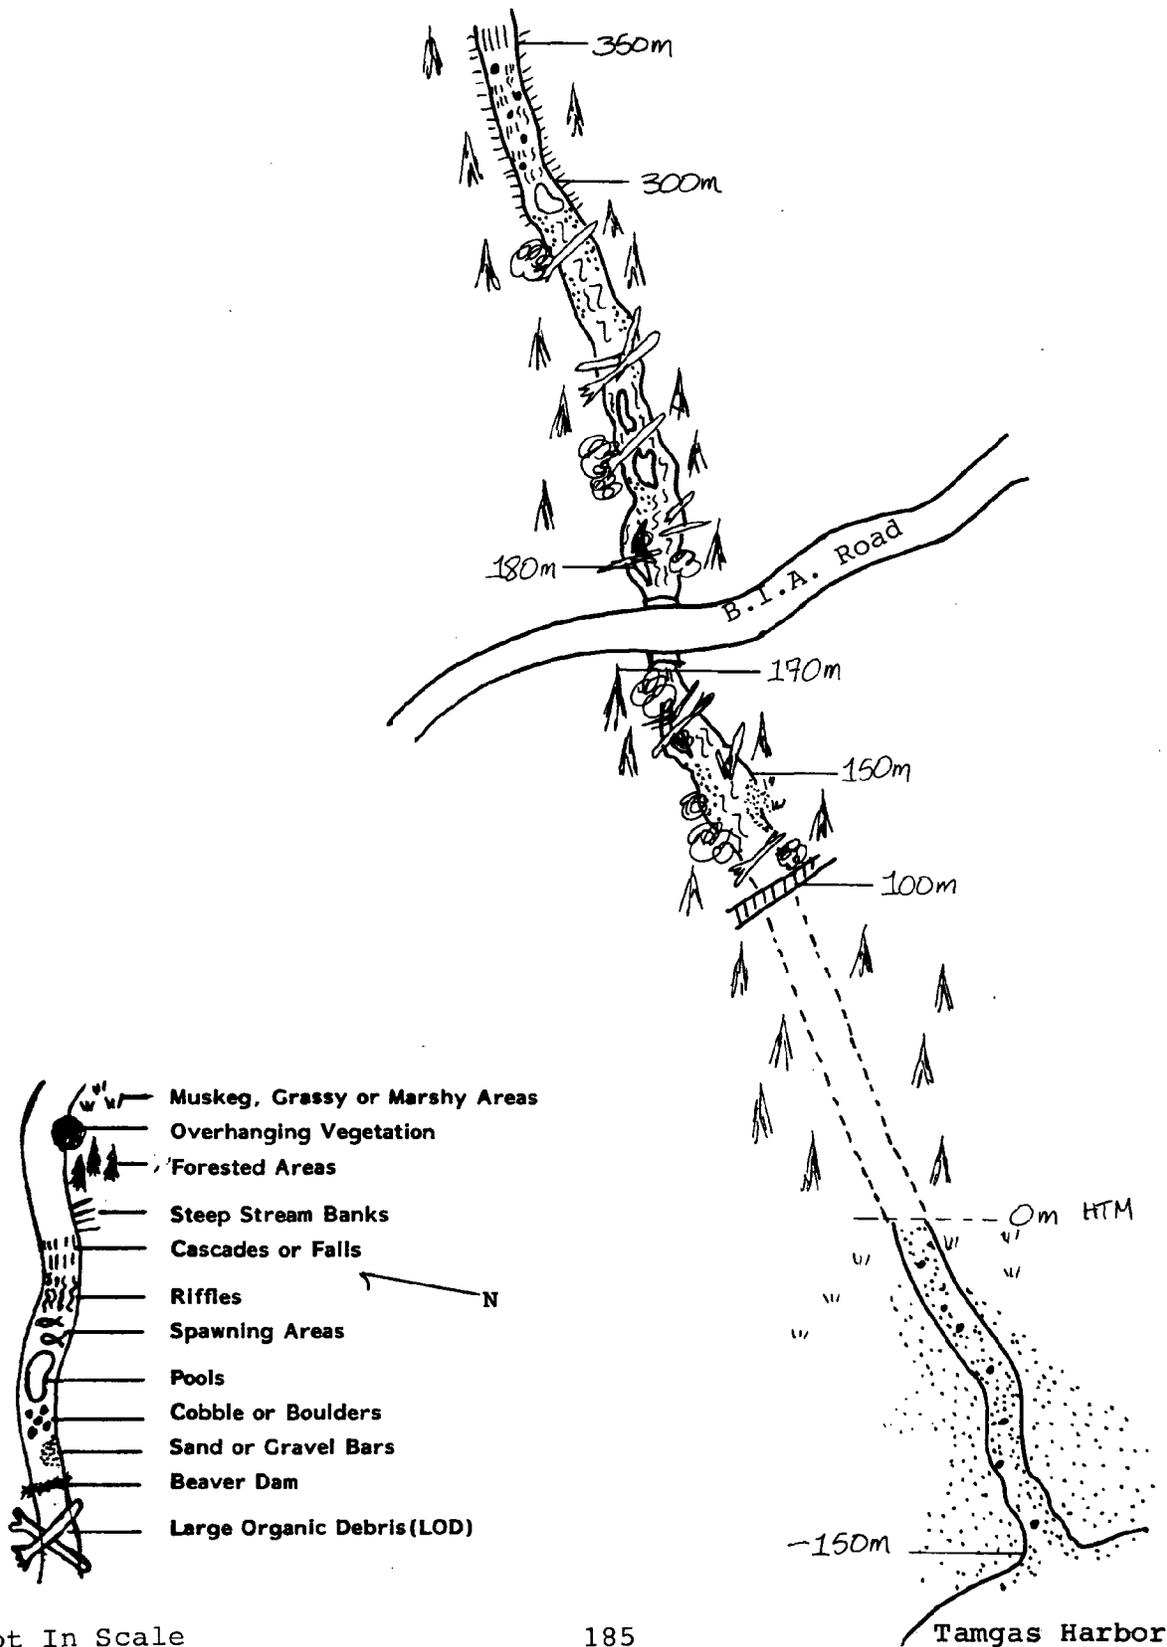

Recommended Escapement

Because of the creeks flashiness, probably only pink and chum salmon make use of it. Recommended escapement based on usable spawning area is 400 pink and 20 chum spawning pairs.

Potential Production Summary

Because of the creeks flashiness, egg survival is low and a 1.2% egg-fry survival rate will be assumed. Potential production is estimated at 142 pinks and 12 chum returning to Annette Island.

Figure 36. TRAIL CREEK

Not In Scale

Tamgas Harbor

TRAIL CREEK

Watershed No. 403-01
Stat. No. 101-26-018

- 150-0m High Tide Mark (HTM) at 0m, Average Stream Width (ASW) = 4.m; bottom composition: 40% large cobble, 20% usable gravels and 40% small boulders (120m² spawning area).
- 0-100m Stream completely sinks into cobbles (no flow on the surface). Old bridge at 100m.
- 100-170m ASW = 1.75m, ASD = .1m, 5m wide gravel bar mixed with cobble. At 160m begins heavy LOD due to road construction and off channel areas. At 170m is a road culvert (under Tamgas Hatchery Road) that is a possible barrier at low flows.
- 180m Braided stream channel with evidence of flashiness.
- 180-300m Lots of heavy LOD and porous gravels (probably a lot of flow is lost to subsurface flow).
- 300m Pool in bedrock is 2 x 3m and .75m deep with granodiorite banks and a bedrock stream bottom.
- 350m 20m high barrier falls. From 300m, gradient is steep and bottom is all large cobble and small boulders.

Spawning Area:

Intertidal approximately 120m² area.
Above HTM, approximately 70m² is available that is probably usable only at high flows.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Tent Creek	101-26-019	403-02
<u>Stream</u>	<u>Number</u>	<u>Geocode</u>
Flows W into Tangas Harbor, 1 mi long. Tent Lake and mountain run-off./ Alpine lake and forested mountain

<u>Total Alkalinity</u>	<u>Total Hardness</u>	<u>Dissolved Solids</u>	<u>Other/Overall</u>				

Spawning Area

Below culvert: 85% bedrock, 5% boulder, 4% rubble, 3% cobble, 2% gravel, 1% pebble, trace sand.

Overall Stream Bottom Composition

Minimal
Gravel Compaction

Limited - large rock and boulder dominate substrate.

Spawning Area Available Above High Tide Mark (HTM)

None

Intertidal Spawning Area

Rearing Area

Pools occur in 15% of creek. to .9m / -- 3m diameter or smaller

Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range

Heavy LOD and overhanging vegetation, a few undercut banks.

Available Cover

Sparse - some diptera and ephemeroptera observed.

Aquatic Invertebrates/Available Food Source

Moderately abundant - periphyton and some aquatic mosses on rocks.

Aquatic Vegetation

Berries and alder with a spruce, hemlock, cedar canopy.

Terrestrial Vegetation

Intense - 99% due to canopy, thick overhanging vegetation, and topography.

Shading

Some available due to heavy LOD and overhanging vegetation; however, flashiness of creek limits rearing.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

No known use of creek by fish.

Use by Fish

None known - area was used during World War II (old pipeline and campsite are present).

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Many creek barriers (3m one at HTM - 11 barriers total recorded by USFWS) prevent use of creek by salmon and the great expense to put in a fish passage could probably not be justified due to the small amount of spawning area. No improvements or enhancement is recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
------	---------	------	--------------	------	----------

Survey(s) and Dates Conducted

C. Huntington, 6/20/81 and USFWS, 7/1/74

Recommended Escapement

None made.

Potential Production Summary

No production potential was conducted because no accessible salmon spawning area exists. Trout utilize this creek.

Historical Escapement/Fish Observed

	Date	Species	Size	Numbers-Live	Dead	Comments
	8/6/80	Sockeye	Adults	60	--	Seen in creek and above in Lake.
	6/11/81	None Seen

As of	11/10/81	Pinks	Adults	2322 (males)	--	Tamgas Hatchery Weir Count Most of pinks, chum and many of the coho were hatchery reared. Sockeye and steelhead number is from natural production. (More coho are still coming in.)
				2626 (females)	--	
		Chum	Adults	143 (males)	--	
				130 (females)	--	
		Sockeye	Adults	800	--	
		Coho	Adults	1134	--	
		Coho	Jacks	333	--	
		Steelhead	Adults	13	--	
		Dolly Varden	Adults	Hundreds	--	

Survey(s) and Dates Conducted

C. Huntington and E. Biggs, 6/11/80 and USFWS, 7/26/71

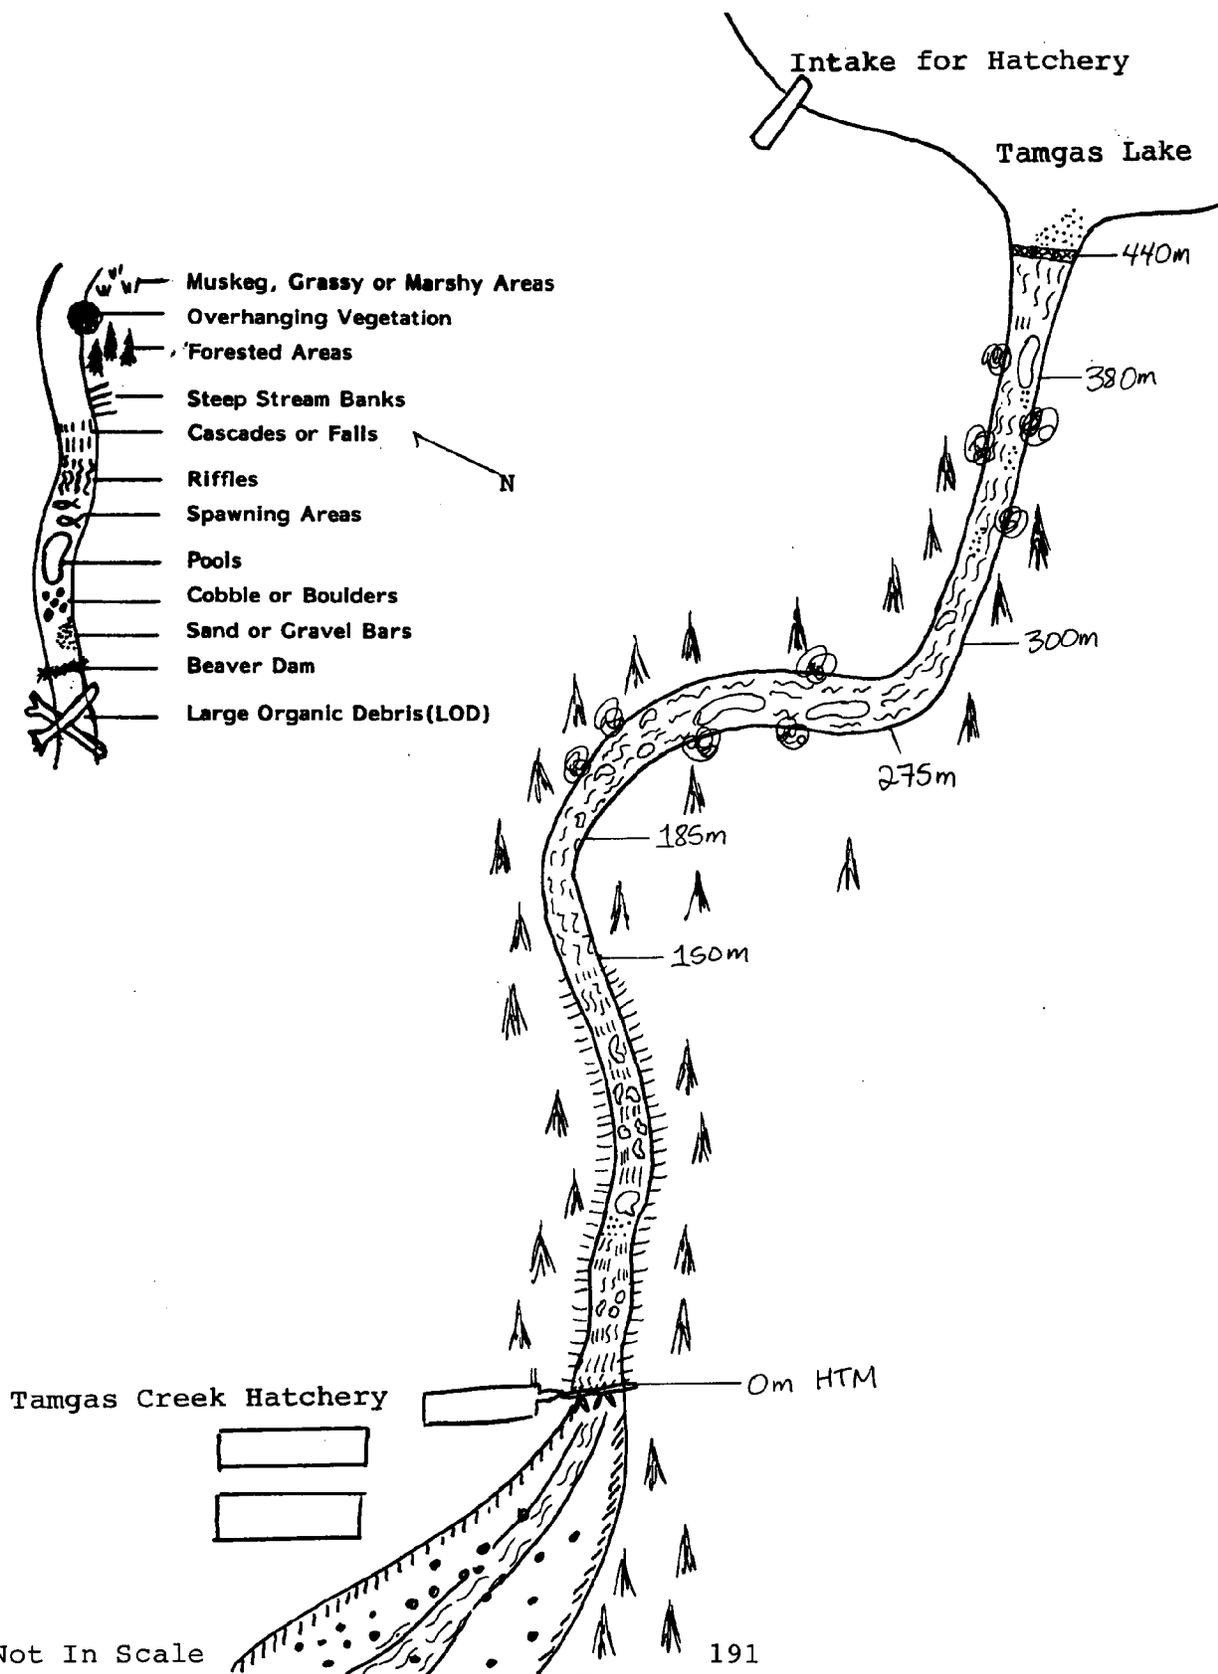

Recommended Escapement

Sockeye are not allowed in the lake anymore due to hatchery disease control procedures, so no escapement recommendations will be made for them. Other salmonids namely coho, utilize this creek only as a migration passage on their way to upper lake tributaries. No recommendations will be made.

Potential Production Summary

Limited to trout, Dolly Varden and steelhead from the creek itself. Other production comes from upper tributaries, Tamgas Lake and Tamgas Creek Hatchery.

Figure 37. LOWER TAMGAS CREEK

LOWER TAMGAS CREEK

Watershed No. 402-01
Stat. No. 101-26-025

- 0m High Tide Mark (HTM), fish weir is here. Below, intertidal area is predominately cobble and boulders, no spawning area.
- 0-150m Cascades and falls (passable) with a few deep plunge pools (one pool has a gravel tailout available for spawning.
- 150-185m Deep run.
- 185-275m Two large pools occur between a deep run.
- 275-300m Riffles and pools.
- 300-380m Riffles and runs with a small amount of angular spawning gravels of fair quality. A bedrock pool occurs at 380m.
- 380-440m Riffles and runs. Gabion dam opening to lake at 440m; there is a small patch of gravel at the head of the Gabion. Hatchery water supply intake is approximately 100m to the north of the creek head.

Spawning Area:

Limited, approximately 25m² maximum (bottom is mainly cobble and boulder).

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Spawning Area

10% boulder, 20% rubble, 40% cobble, 25% gravel, 5% pebble, trace sand, trace organic matter.
 Overall Stream Bottom Composition

Gravel Compaction

Excellent spawning area, approximately 1100m² area is currently available (USFWS recommended allowing Spawning Area Available Above High Tide Mark (HTM) 1500 sockeye spawners escapement).

Not applicable.

Intertidal Spawning Area

Rearing Area p:r = 25-75%, riffles are less than .45m deep, few pools (they occur behind LOD and near banks). -- / to 1.2m Small to moderate in size

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
Little overhanging vegetation - some pools available,	some undercut banks	and side channels.

Available Cover

A few - diptera and trichoptera larvae seen.

Aquatic Invertebrates/Available Food Source

None

Aquatic Vegetation

Muskeg grasses; spruce and hemlock.

Terrestrial Vegetation

70% shading due to brush and timber.

Shading

Some cover is available, but rapid creek velocity and bouldery cascades limit area - plenty is available

Extent and Quality of Rearing Area

in lake below.

Reported and Suspected Use of Stream by Fish and Fishermen

Coho, cutthroat and Dolly Varden use stream; sockeye used to use it (before Weir was put in).

Use by Fish

Possible light subsistence fishing, but doubtful that fishing still occurs.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

No habitat improvement is recommended (a fish passage over the falls would not increase production that much). They stated that the creek was definitely underutilized (recommended 1500 sockeye escapement).

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/20/71	Sockeye	Adult (average 6 lbs.)	1204	--	In creek
	Sockeye	Adult	100		At creek mouth
8/19/72	Sockeye	Adult	450	--	
8/73	Sockeye	Adult	35	--	
8/1/74	Sockeye	Adult	194	--	
	Coho	Fry	Few	--	Seen below lower falls.
8/6/80	Sockeye	Adults	60	--	Probably utilized this creek and Lea Creek (observed in Lower Tamgas Creek).
Fall '81	See Weir Count for Lower Tamgas Creek				

Survey(s) and Dates Conducted

USFWS, 9/20/71, 8/19/72, and 8/1/74

Recommended Escapement

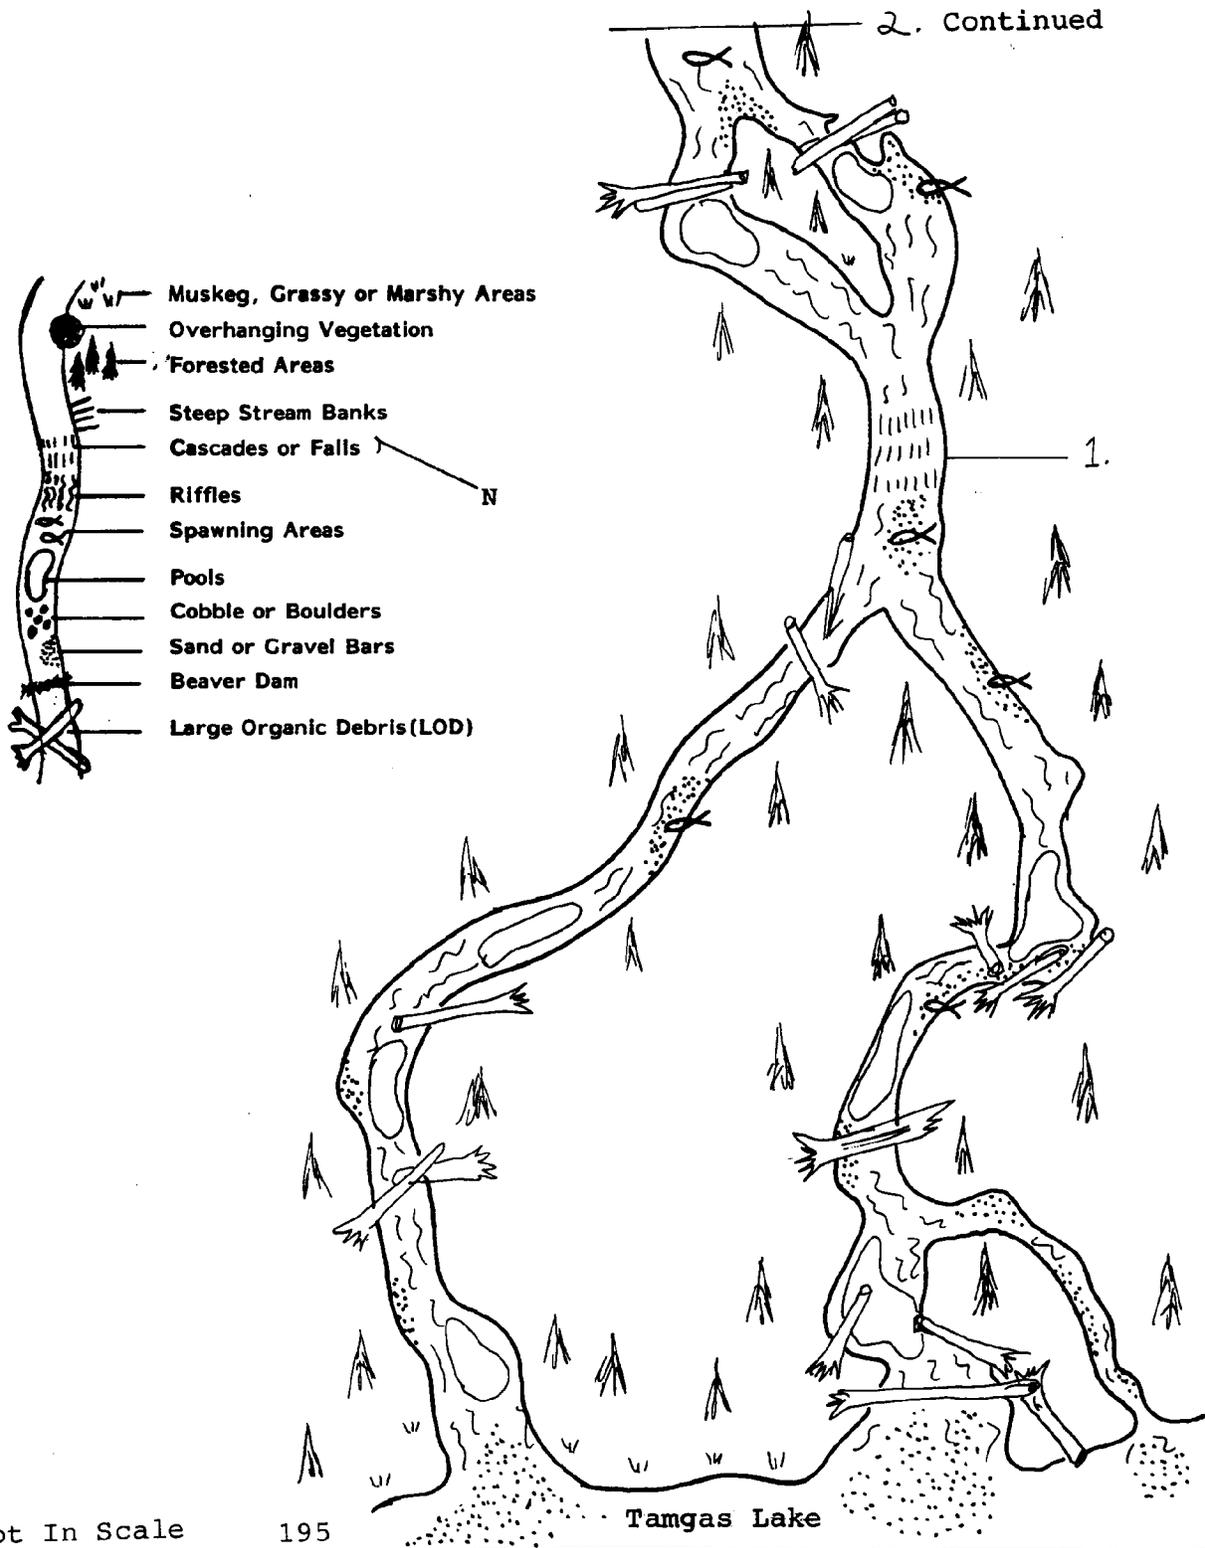

Based on the USFWS surveys, 94 coho spawning pairs could utilize this creek (however, that estimate is probably high). Sockeye are not allowed to utilize Tamgas Lake anymore.

Potential Production Summary

(Combined with Lea Creek)

530 coho could potentially return to Tamgas Creek resulting from production in this creek (assuming a 10% egg-fry survival rate since gravel quality is unknown).

Intertidal Spawning Area

Rearing Area

Fairly abundant pools. In forks = .30m/to 1.2m
 1m / to 1.75m In tributary - 2 x 3m/ --

Pool/Riffle Frequency (P:R Ratio) **Ave. Pool Depth/Range** **Ave. Pool Size/Range**
 A fair amount of LOD exists along with some undercut banks and root tangle.

Available Cover
 Abundant below 750m, sparse above 750m: trichoptera (especially Glossosoma), ephemeroptera and diptera
 observed.

Aquatic Invertebrates/Available Food Source
 Abundant algae and moss on rocks and filamentous algae.

Aquatic Vegetation

Muskeg vegetation and forest.

Terrestrial Vegetation

60% due to topography, a little riparian vegetation and canopy (up to 95% in tributaries).

Shading

Some LOD, overhanging vegetation, undercut banks and pools create a fair amount of rearing area, the

Extent and Quality of Rearing Area

best occurring from 400-575m; however, rearing area is a limiting factor to coho production, not spawning
 area. More rearing and spawning area is available in tributaries.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, coho and cutthroat currently utilize this creek.

Use by Fish

Light subsistence fishing with some hunting in the fall occurring.

Use by Fishermen

Wildlife Present

Deer sign abundant - Canada Geese roost in slough.

Comments and Recommendations

Good quality spawning and rearing area occurs in both the main channel and in the forks. A fish
 passage at 750m could open up more spawning and rearing areas, a benefit: cost study would be
 recommended. As it is, the creek produces some, but not alot of pinks and chum and can only
 accommodate a few coho spawning pairs.

Historical Escapement / Fish Observed

Survey(s) and Dates Conducted

C. Huntington, 6/9/81 and USFWS, 8/10/73

Recommended Escapement

Recommended escapement based on currently available spawning area is 2200 pinks, 145 chum and 10 coho spawning pairs. Historical escapements indicate a low survival of offspring, whether due to poor gravel quality and other detrimental freshwater factors, or low marine survival.

Potential Production Summary

Based on the above escapements and assuming a low egg-fry survival rate of 1.2% due to the poor gravel quality, production potential estimates are: 785 pinks, 86 chum and 7 coho returning to Annette Island. Obviously, this is a conservative estimate, as escapements have exceeded that in previous years.

WEST CAMPBELL CREEK

Watershed No. 311-02
Stat. No. 101-24-030

- 400m Point at which West Campbell Creek joins East Campbell Creek in Campbell Slough.
- 225m Creek forks, tributary is the East Fork of West Campbell Creek, 80% spawning area intertidally to 0m.
- 0-50m (East Fork) High Tide Mark (HTM) at 50m, creek flows through small cascades.
- 150m (East Fork) Passable debris jam.
- 160m (East Fork) Debris pile.
- 200m (East Fork) Probable barrier, 40° rise in 5m, over bedrock cascades.
- 0-475m (East Fork) Mainly bedrock cascades, 4-10% gradient, .6 cfs flow; creek is 85% shaded.
- 475-800m Lower stream gradient and good spawning (less than 1.5%) and rearing habitat (muskeg area); 8 inch trout spotted near 800m. (End of survey.)
- 0m (Main Channel) HTM.
- 0-750m Average Stream Width (ASW) = 4.5m, 20% gravels overall, some areas, 300-325m and 350-385m are 90% bedrock; tributary (North Fork West Campbell Creek enters at 375m); best rearing and spawning area (over 75% spawning gravels) is from 400-575m. Log jam with .3m drop at 650m. At 750m is a 2m high probable barrier cascade with a 4% gradient above it; probably no coho get above this.
- 0-50m (North Fork) 2m falls without plunge pool at 50m, fork begins at 375m, main channel.
- 550m (North Fork) Debris jam, probable barrier.
- 600m (North Fork) Debris jam barrier.
- 50-750m (North Fork) Gradient lowers, good rearing and fair spawning areas.
- 750-850m (Main Channel) 90% bedrock.
- 1100-1160m 90% bedrock, a 2m high and 10m wide bedrock cascade occurs at 1100m with a 60m of bedrock channel to 1160m.
- 1450m .5m falls with 2.5m plunge pool.
- 1850m Tributary comes in, no spawning area, but some rearing area.
- 2200m Tributary comes in, no spawning area, but some rearing area.
- 2300m Series of cascades.
- 2550m Debris jam with deep plunge pool.
- 2650m 1m falls with deep plunge pool.
- 2725-2800m Passable falls with cascades.
- 2950m 3.3m high debris jam with gravels and a definite barrier.
- 750-2950m 13% gravels overall, ASW = 2.75m.
- 3100m Alot of boulders and bedrock, no more good spawning or rearing habitat here or above.
- Spawning Area: Intertidal Area 650m² spawning area available.
Above HTM, 0-750m 675m² spawning area available.
750-2950m 605m² potential area above present barrier.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

East Campbell Creek		101-24-032		310-01	
Stream		Number		Geocode	
Flows SW into Campbell Slough, 2.7 mi long.		Mountain run-off./ hillsides and forested muskeg areas. (195 acres)			
Location		Origin		Watershed Type	
6/8/81		falls may block pink and chum.		Moderate to low. +2.5 ft

4°		3.5 cfs / up to 19 cfs/		1 fps / --	
Ave. Gradient		Flow / Range		Ave. Velocity/Range	
Dirt and rock heavily vegetated, some undercutting/Relatively stable./ Three with a fork at 3600m					
Streambank Composition		/ Stability		Tributaries	
Water Quality 8/15/73:		11.1C		13.4C	
150m above mouth		11.1C		9C	
Sample Site		Temp.-Air		Temp.-Water	
17.1ppm (8/15/73)		--		--	
Total Alkalinity		Total Hardness		Dissolved Solids	
				Other/Overall	

Spawning Area

20% spawning gravels (much of which is angular - slate), 20% cobble, 20% boulders, 30% bedrock, 10% rubble, and trace fines - many gravel bars occur.

Overall Stream Bottom Composition: Some fines and some angular gravels, but relatively clean in general.

Gravel Compaction

781m² area total is available.

Spawning Area Available Above High Tide Mark (HTM)

An excellent intertidal spawning channel exists - 650m² total area.

Intertidal Spawning Area

Rearing Area pools frequent and caused by bends in stream, boulders, and fallen timber.

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
Some LOD occurs, upstream, overhanging vegetation gets thicker.	.9m / up to 1.5m	4.5 x 4.5m / --

Available Cover

Abundant

Aquatic Invertebrates/Available Food Source

Some algae

Aquatic Vegetation

Thick riparian vegetation (thick alders) - in a cedar and spruce canopy.

Terrestrial Vegetation

75% shading mainly from the riparian vegetation; the rest is from canopy.

Shading

Upstream (upper end) alot exists, especially in off channel areas under LOD, thick vegetation and in

Extent and Quality of Rearing Area

side pools.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, coho and probably cutthroat utilize this creek.

Use by Fish

Little to no subsistence fishing occurs. Hunters use creek and slough.

Use by Fishermen

Wildlife Present

Many deer tracks (3 spotted) - Canada Geese roost in slough.

Comments and Recommendations

This creek could be a major producer on Annette Island. Alot of good to excellent quality spawning and rearing area occurs. No habitat improvements are recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
8/15/73	Pink and Chum	Adults	--	--	Spotted, not counted.
1974	Pinks	Adults	4556	--	USFWS Estimated Total Escapement
1975	Pinks	Adults	22,319	--	USFWS Estimated Total Escapement
1975	Pinks	Adults	9319	--	USFWS Estimated Total Escapement
6/8/81	Coho	Fry	Numerous		
9/1/81	No fish seen in creek mouth or slough.				(aerial count)
9/25/81	Pink		25	6	(underescapement - why? - possibly
	Chum		--	--	due to commercial fishing at mouth?)

Survey(s) and Dates Conducted

E. Biggs, J. Yuska, 6/9/81 and USFWS, 8/15/73

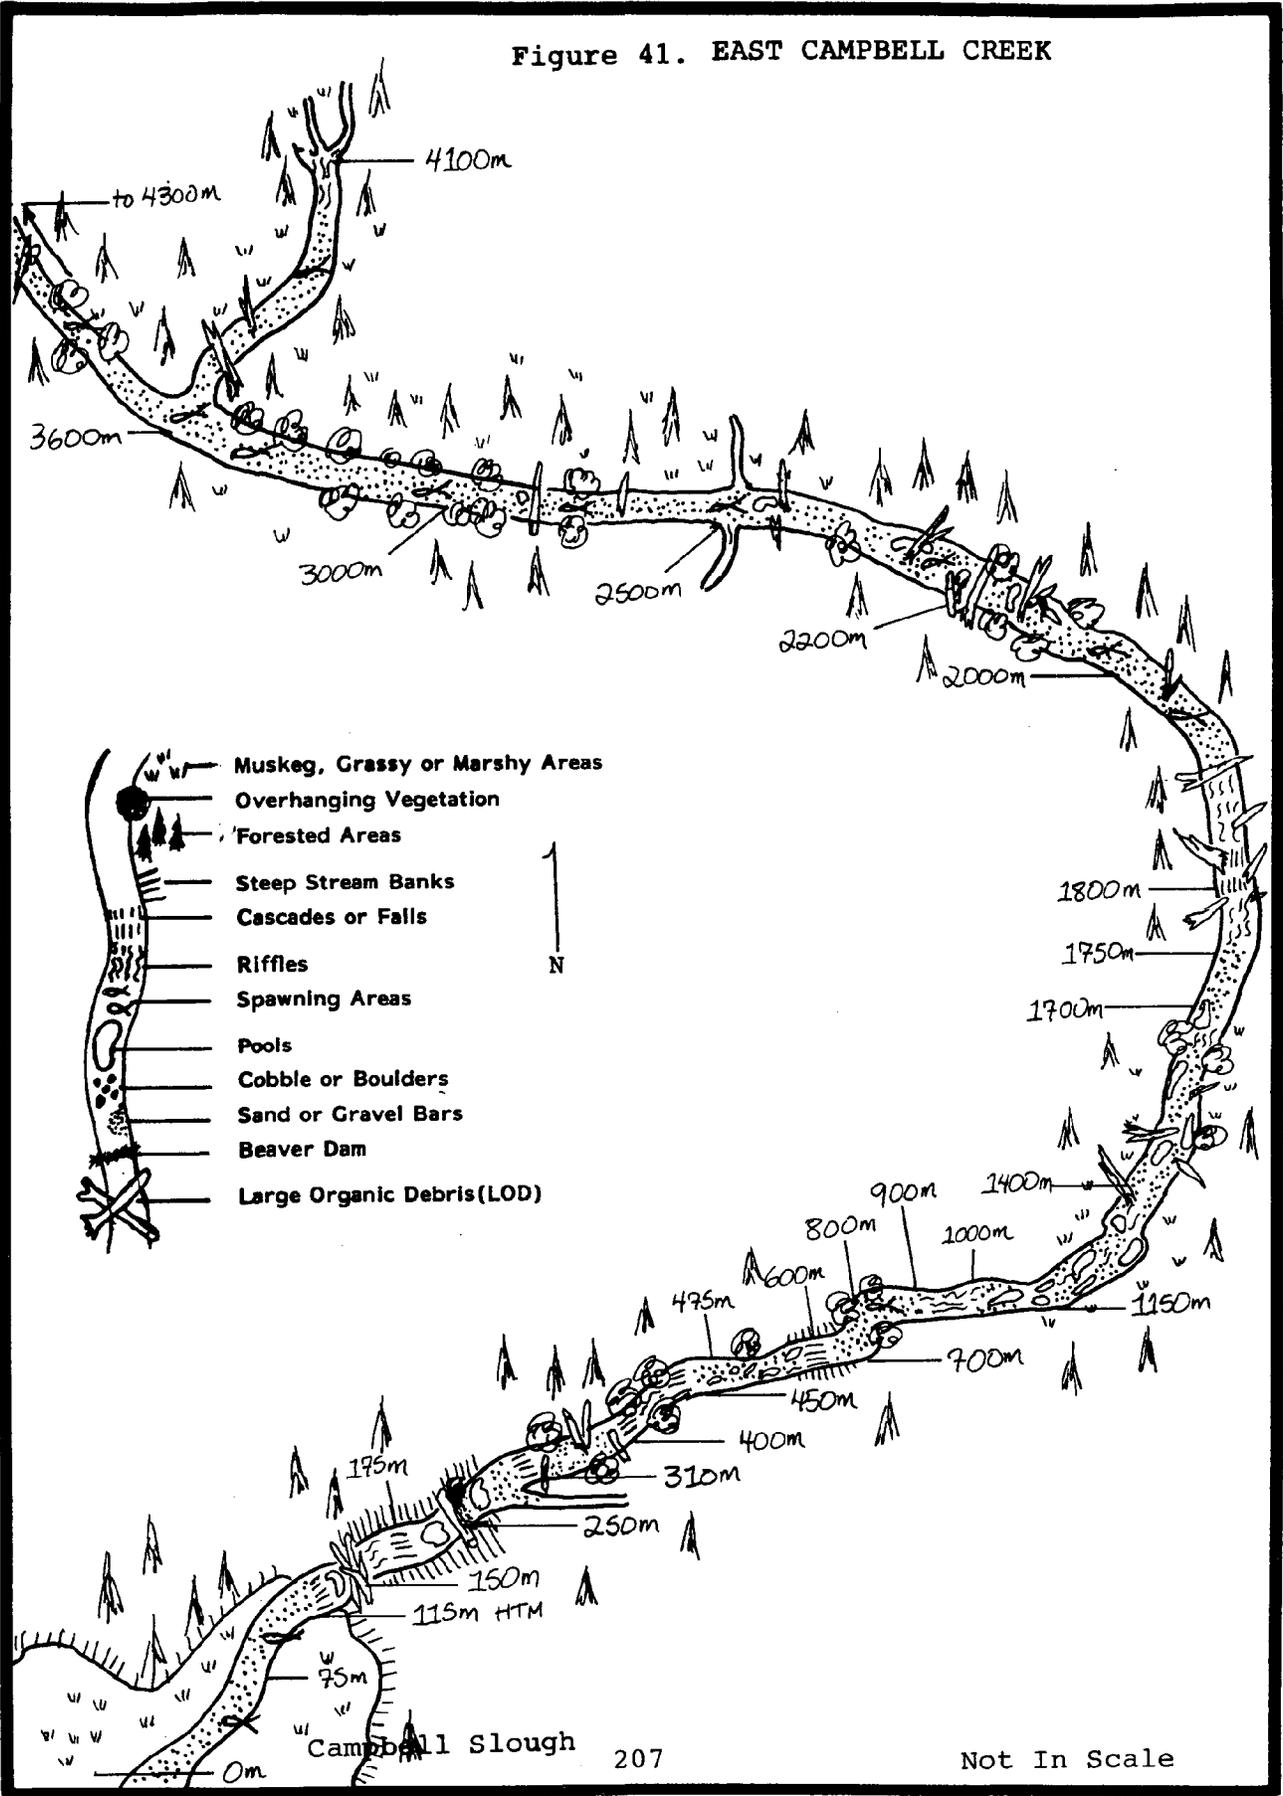

Recommended Escapement

Recommended escapements for this creek based on available and accessible spawning area and coho rearing area are 4300 pinks, 235 chum and 150 coho spawning pairs.

Potential Production Summary

An overall survival rate of 10% egg-fry will be assumed to the fair-good quality gravels occurring. Production potential for this creek is estimated at 13,000 pinks, 1200 chum and 850 coho returning to Annette Island. Obviously this potential can be exceeded in good years; however, it seems that creek production has been much lower than potential in recent years.

Figure 41. EAST CAMPBELL CREEK

EAST CAMPBELL CREEK

Watershed No. 310-01
Stat. No. 101-24-032

- 600m Campbell Slough mouth.
- 0m Beginning of excellent intertidal spawning area.
- 0-75m Average Stream Width (ASW) = 8m, Average Stream Depth (ASD) = .08m, 90% usable gravels (540m² spawning area).
- 75-115m ASW = 5.5m, 50% usable gravels (110m² spawning area), High Tide Mark (HTM) at 115m.
- 115-150m Heavy LOD, less than 5% usable gravels.
- 150-250m Bedrock cascades (low gradient) and pools, Heavy LOD at 150m with less than 5% gravels above. ASW = 5m, ASD = .3m. At 250m tree across creek may be a barrier at low flows - creek has steep stream banks; 6m wide pool, 1m deep above log.
- 250-310m 5% spawning gravels above pool at 250m, first order tributary enters (very steep gradient, flows over bedrock). At 310m, top of bedrock cascade with alot of gravel bars, LOD, root wads, generally good rearing area.
- 310-400m ASW = 4m, ASD = .2m, with 7m long gravel bars, 35% spawning gravels.
- 450m 1.5m falls here may be a barrier to pink and chums.
- 475m ASW = 3m, ASD = .25m, alot of pools here with less than 5% usable gravels (poor quality gravels, too flat and angular).
- 600m Cascading falls over bedrock (not a barrier).
- 700m ASW = 3.5m, 5% gravels; coho fry observed here.
- 800-900m ASW = 4.5m, low gradient, 30% spawning gravels with gravel bars.
- 900m ASW = 4.5m, gravels decrease to 5%, numerous "backwater" areas available for rearing.
- 1150m ASW = 3.5m, ASD = .3m, less than 5% spawning gravels.
- 1400m Low gradient, 5% spawning gravels in pockets.
- 1400-1700m Muskeg area (much skunk cabbage in and around creek).
- 1700-1750m ASW = 3.5m, 30% spawning gravels.
- 1800m 1.25m cascade through a fair amount of LOD.
- 2000m ASW = 3m, ASD = .08m, 90% usable round gravels including 3m gravel bars.
- 2200m Excellent spawning and rearing area with alot of off channel areas with 6m wide pools, 1m deep; 75% shading.
- 2500m Muskeg tributary enters, with 50% usable spawning gravels.
- 3000m Stream banks flat in muskeg with a narrow band of riparian vegetation, alders, cedars, and spruce. There are still 50% usable gravels, but they have some fines mixed in.
- 3600m Stream splits into two 2m wide tributaries, each .08m deep; 50% usable gravels, cedar dominate with riparian vegetation.
- 4100m (East Fork) Gravel gone as creek flows into muskeg and fine sediments; 50% gravels from 3600-4100m.
- 4300m (West Fork) Gravel gone, bottom all fines; 50% gravels from 3600-4300m.

Spawning Area: Intertidal area 650m² Total Area
Above HTM 7811m² Total Area

Spawning Area

40-60% gravel, 10% cobble, 10% boulder, 20% bedrock (foliated - high in quartz), some sand.

Overall Stream Bottom Composition

Minimal - good, clean gravels here.

Gravel Compaction

Some excellent quality spawning channels exist with some occurrences of gravel bars, approximately 3222m² Spawning Area Available Above High Tide Mark (HTM) area is available.

80% gravels intertidally, 720m² available area good quality.

Intertidal Spawning Area

Rearing Area Some deep pool exist from 36-3800m

p:r = 1.5-2 in lower reaches.	.55m / up to 1.5m	10m in diameter / --
<u>Pool/Riffle Frequency (P:R Ratio)</u>	<u>Ave. Pool Depth/Range</u>	<u>Ave. Pool Size/Range</u>

LOD increases as you go upstream with a few undercut banks and deep pools; a moderate mount occurs.

Available Cover

Relatively abundant, especially upstream; diptera, heptagenids and mayflies observed.

Aquatic Invertebrates/Available Food Source

Sparse

Aquatic Vegetation

Currant, salmonberry, devil's club and alder under a spruce, cedar and a few hemlock canopy.

Terrestrial Vegetation

40% at 350m, average overall is about 50%, much of it due to overhanging vegetation.

Shading

Some, but not alot, of good rearing exists in the main channel - alot of the available area exists in

Extent and Quality of Rearing Area

the tributaries and in a few braided channels.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum and coho utilize this creek.

Use by Fish

Some light subsistence fishing occurs.

Use by Fishermen

Wildlife Present

Some beaver activity is evident.

Comments and Recommendations

Annette Point Creek is one of the major salmon producing creek on Annette Island due to the magnitude and quality of the spawning and rearing areas and due to its large size. No improvements are recommended.

Recommended Escapement

Recommended escapement based on available spawning area and rearing area is 2670 pink, 175 chum and 25 coho spawning pairs.

Potential Production Summary

With the excellent quality gravels occurring a 20% egg-fry survival rate can be assumed. 15,860 pinks, 1730 chum, 280 coho could potentially return to Annette Island based on the above escapements.

Figure 42. ANNETTE POINT CREEK

Not In Scale

-150m

ANNETTE POINT CREEKWatershed No. 309-01
Stat. No. 101-24-079

- 150-0m 80% spawning gravel (720m² of spawning area) High Tide Mark (HTM) at 0m.
- 0-100m Bedrock riffle.
- 100-250m Spawning gravels on bars (8 x 4m = 32m² area), with 10m wide pools.
- 350m Average Stream Depth (ASD) = .2m; side channels have excellent gravels and cover (from LOD and banks). Gravel bar area, 14 x 4m = 56m² spawning area.
- 600m Steep banks (40 ft high).
- 650-900m Average Stream Width (ASW) = 11m, ASD = .1m, bottom composition: 10% gravel, 50% large cobble, 20% bedrock, 20% boulder, (1275m² available spawning area). Tributary at 900m (second order) with a .5 cfs flow, good rearing habitat and a 30m² spawning area.
- 900-950m 11m² gravel bar, with 15% usable gravel bottom (52m² area total).
- 1050m 5% spawning area; 20m² area.
- 1050-1200m Alot of LOD, 15% usable gravels (90m² spawning area).
- 1200-1350m Braiding occurs with excellent rearing habitat, ASW = 4m, ASD = .2m (192m² spawning area).
- 1350-1600m ASW = 6m, ASD = .15m, 15% gravels (225m² spawning area); braiding ends.
- 1600-1700m Bouldery cascade flowing through a gorge; 1.3m falls at 1700m, but it is not a barrier to coho (but could be to pinks and chums).
- 1800m Gorge ends, 1.5m fall above.
- 1850-2000m ASW = 4.5m, ASD = .2m, 20% gravels (135m² spawning area).
- 2000-2100m Channel braids under LOD with alot of rearing habitat (coho fry seen); ASW = 11m, ASD = .09m; 80% spawning gravels including 11m wide gravel bars (880m² spawning area).
- 2100-2200m ASW = 5m, ASD = .2m - no braiding (50m² spawning area).
- 2200-2350m More braiding occurs, ASW = 11m, ASD = .09m, 80% spawning gravels (880m² spawning area).
- 2350-2400m Braids end, 10% usable gravels (120m² spawning area).
- 2400m Bedrock cascade.
- 2425m Braiding begins, ASW = 5m, ASD = .15m, 80% gravels (200m² spawning area).
- 2500m Bedrock cascade.
- 2650m Bedrock ends, ASW = 5m, ASD = .2m, 10% gravels (25m² spawning area).
- 2700m 1.3m cascade.
- 3000m 1m bedrock cascade.
- 3100m 2m high, 10m long (very shallow) bedrock cascade.
- 3300m Cascades continue.
- 3500m LOD, less than 5% gravels.
- 3600-3800m Pockets of gravel (less than 5% total) between cascades and deep pools (50m² area total).
- 3800m Steep gradient; gorge begins above this point.
- 4300m 10m falls barrier.
- Spawning Area: Intertidal 720m² spawning area.
Above HTM 3222m² spawning area.

Spawning Area

About 20% gravels, 30% pebbles, 10% boulders, and cobble, 20% sand, 20% silt.

Overall Stream Bottom Composition Some, especially near where fines occur.

Gravel Compaction

60m² area exists in the South Fork and 125m² in the North; 187m² area exist total.

Spawning Area Available Above High Tide Mark (HTM)

50% spawning gravels, 300m² total area available.

Intertidal Spawning Area

Rearing Area Pools are sparse, but some deep pools are created in muskeg areas.

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
By undercut banks and muskeg "land bridges" not much there.	--	--
Available Cover	--	--

Aquatic Invertebrates/Available Food Source

Alot of moss occurs on rocks in the lower reach.

Aquatic Vegetation

Huckleberry, azalea, skunk cabbage, and grasses in a cedar, spruce canopy.

Terrestrial Vegetation

40% overall, 10% due to banks, and 30% due to vegetation.

Shading

Not much is available due to lack of cover and pools, and small size of creek.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Probably only utilized by pink and chum.

Use by Fish

No fishing is known on this creek.

Use by Fishermen

Wildlife Present

None

Comments and Recommendations

This creek probably produces mainly pinks and does not produce large numbers. No improvements are recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/20/81	None seen				

Survey(s) and Dates Conducted

J. Yuska, 6/20/81

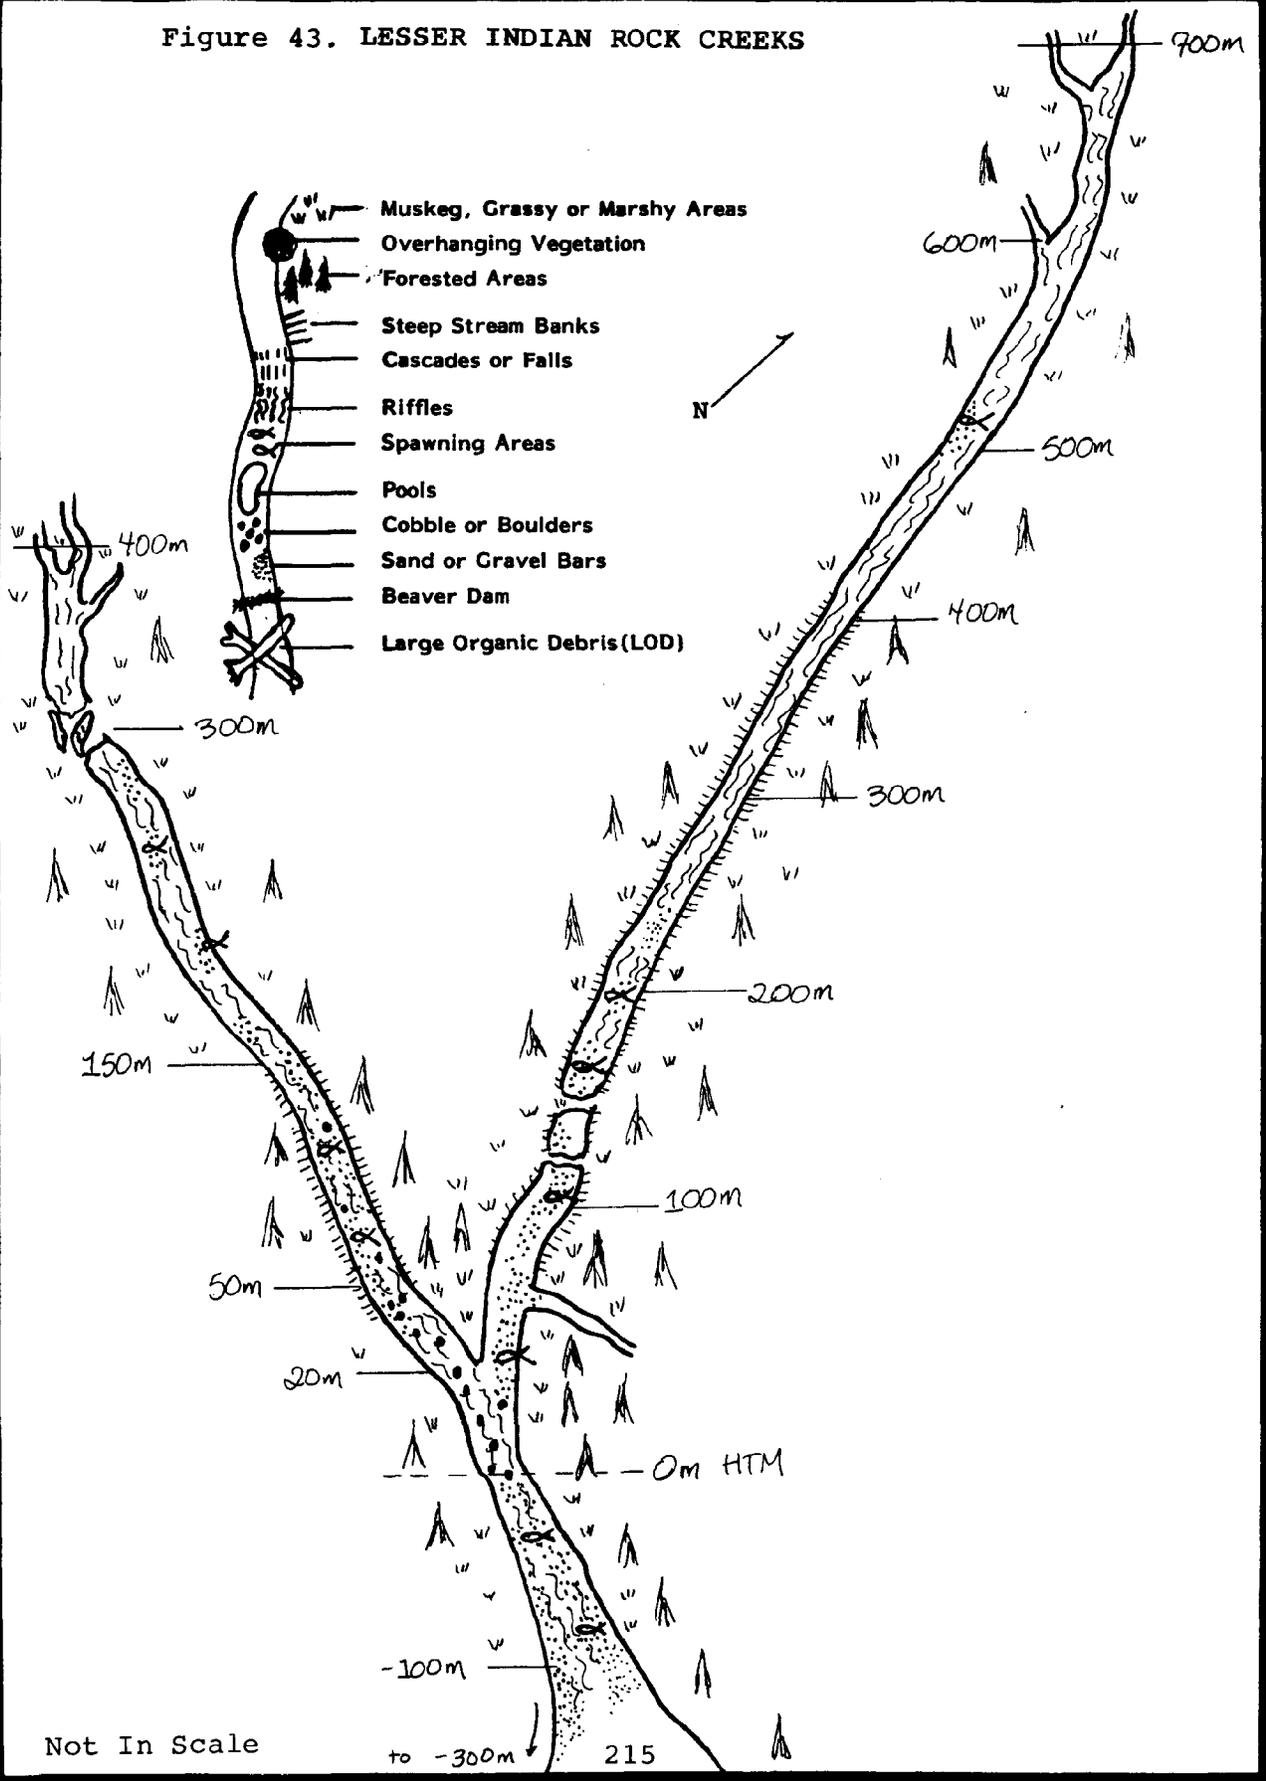

Recommended Escapement

Based on available spawning area, and gravel quality, recommended escapement is 812 spawning pairs of pinks only.

Potential Production Summary

Due to the compacted gravels, a 1.2% egg-fry survival rate will be assumed. 290 pinks could return to Annette Island originating from this creek.

Figure 43. LESSER INDIAN ROCK CREEKS

Not In Scale

LESSER INDIAN ROCKS CREEK

Watershed No. 309-02

Stat. No. 101-24-081

- 300m Cabin
- 100-0m Intertidal area, Average Stream Width (ASW) = 6m, 50% spawning gravels. High Tide Mark (HTM) at 0m.
- 0-20m ASW = 5m, 80% boulders and 20% cobble; stream splits at 20m.
- 20-50m (South Fork)
ASW = 2.5m; bottom composition: 50% boulders, 50% cobble, less than 5% gravels.
- 50-150m (South Fork)
ASW = 1.5m, 30% gravels (45m² spawning area).
- 150-300m (South Fork)
ASW = 1m; bottom composition: 10% gravels, 40% pebbles, 10% cobble, 40% sand (15m² spawning area).
At 300m, stream is covered with muskeg "land bridges" (roots and vegetation).
- 400m (South Fork)
Stream splits into muskeg.
- 20-100m (North Fork)
ASW = 3m, stream incised in muskeg like soils, with deep pools and a moderate gradient; bottom composition: 30% sand, 30% gravel, 40% pebbles (72m² spawning area).
- 100-200m (north Fork)
ASW = 1.5m, moderate gradient, pools deep, stream flows through muskeg and under "land bridges"; 30% gravels, old redd observed at 150m, (45m² spawning area).
- 200-300m (North Fork)
ASW = 1m, ASD = .4m, stream deep and narrow, less than 5% gravels.
- 300-400m (North Fork)
ASW = .5m, ASD = .4m; less than 5% gravels.
- 400-500m (North Fork)
ASW = 1m, all mud/silt/sand substrate, no gravels; low gradient. At 500m, 70% pebbles in pockets, 10% gravels (10m² spawning area).
- 600m (North Fork) Less than 5% gravels.
- 700m (North Fork) Stream splits into muskeg.
- Spawning Area: Intertidal 300m² spawning area
Above HTM 187m² spawning area

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Indian Rock Creeks (North & South Forks)		101-24-083	308-01
Stream	Number	Geocode	
Flows SE into Felice Strait, .5 mi long. Steep mountain slope run-off./		Timbered and exposed rock	
Location		Watershed Type	
6/20/81	to 550m above mouth	muskeg. (35 acres in area).	
Date Surveyed		Origin	Flow
5° North Fork/	5.5 cfs North Fork	Barrier falls up both forks.	Moderate Flow
3° South Fork/2-7°	6.5 cfs South Fork/-		+1.5 ft
Ave. Gradient		Barriers	Stage
Steep banks in areas, some undercut banks and moderate		Moderate / up to 2.5 fps/	4m North Fork/--
Flow / Range		1 fps / in North Fork	3m South Fork/--
LOD influence in lower 250m./		Ave. Velocity/Range	Ave. Width/Range
Relatively stable overall.			
Streambank Composition		Stream forks at HTM:	4 tributaries in
/ Stability		Tributaries	South Fork.

Water Quality	8/24/73:	13.3C	11.1C	6.5	Turbid	Brown	--	--
-		10.5C	11.5C	--	Clear / None	Brown	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO₂	
17.lppm (8/24/73)	--	--	--	--	--	--	--	
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall					

Spawning Area

South Fork: 10% bedrock, 5% boulders, 20% rubble, 35% cobble, 20% gravels, 5% pebbles, 5% sand, trace silt.
 Overall Stream Bottom Composition

North Fork: 30% bedrock, 35% boulders, 20% rubble, 15% cobble. Moderate due to fines.
 Gravel Compaction

25m² patchy and of marginal quality in both forks.

Spawning Area Available Above High Tide Mark (HTM)

5% spawning intertidally; approximately 80m² of marginal quality area is available.

Intertidal Spawning Area

Rearing Area Pools occur around bends and under/ .5m North Fork up to 1m
 LOD, p:r = 2:3 (below clay banks- South Fork). .25m South Fork up to .5m -- --

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
--	------------------------------	-----------------------------

A little LOD and a few undercut banks in lower end - limited.

Available Cover

Sparse in both forks.

Aquatic Invertebrates/Available Food Source

Sparse: a little algal growth (filamentous) in the lower end to 50m in the South Fork.

Aquatic Vegetation

Some skunk cabbage, devil's club, currant under a spruce, cedar and hemlock canopy.

Terrestrial Vegetation

5% in lower end (due to banks); above 50m, 85% (bothforks) due to forest and banks and a little riparian

Shading vegetation.

In North Fork, rearing is limited due to swift velocity and lack of cover. In South Fork,

Extent and Quality of Rearing Area

fair habitat occurs in lower 250m due to LOD and undercuts, but swift velocity is limiting - poor above 250m.

Reported and Suspected Use of Stream by Fish and Fishermen

Probably only pinks and chum utilize creek if at all.

Use by Fish

Even though there is a cabin present, no known fishing occurs.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

This creek is of marginal value for salmon production - no improvements are recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
8/24/73	None seen				
6/20/81	None seen				

Survey(s) and Dates Conducted

C. Huntington, 6/20/81 and USFWS, 8/24/73

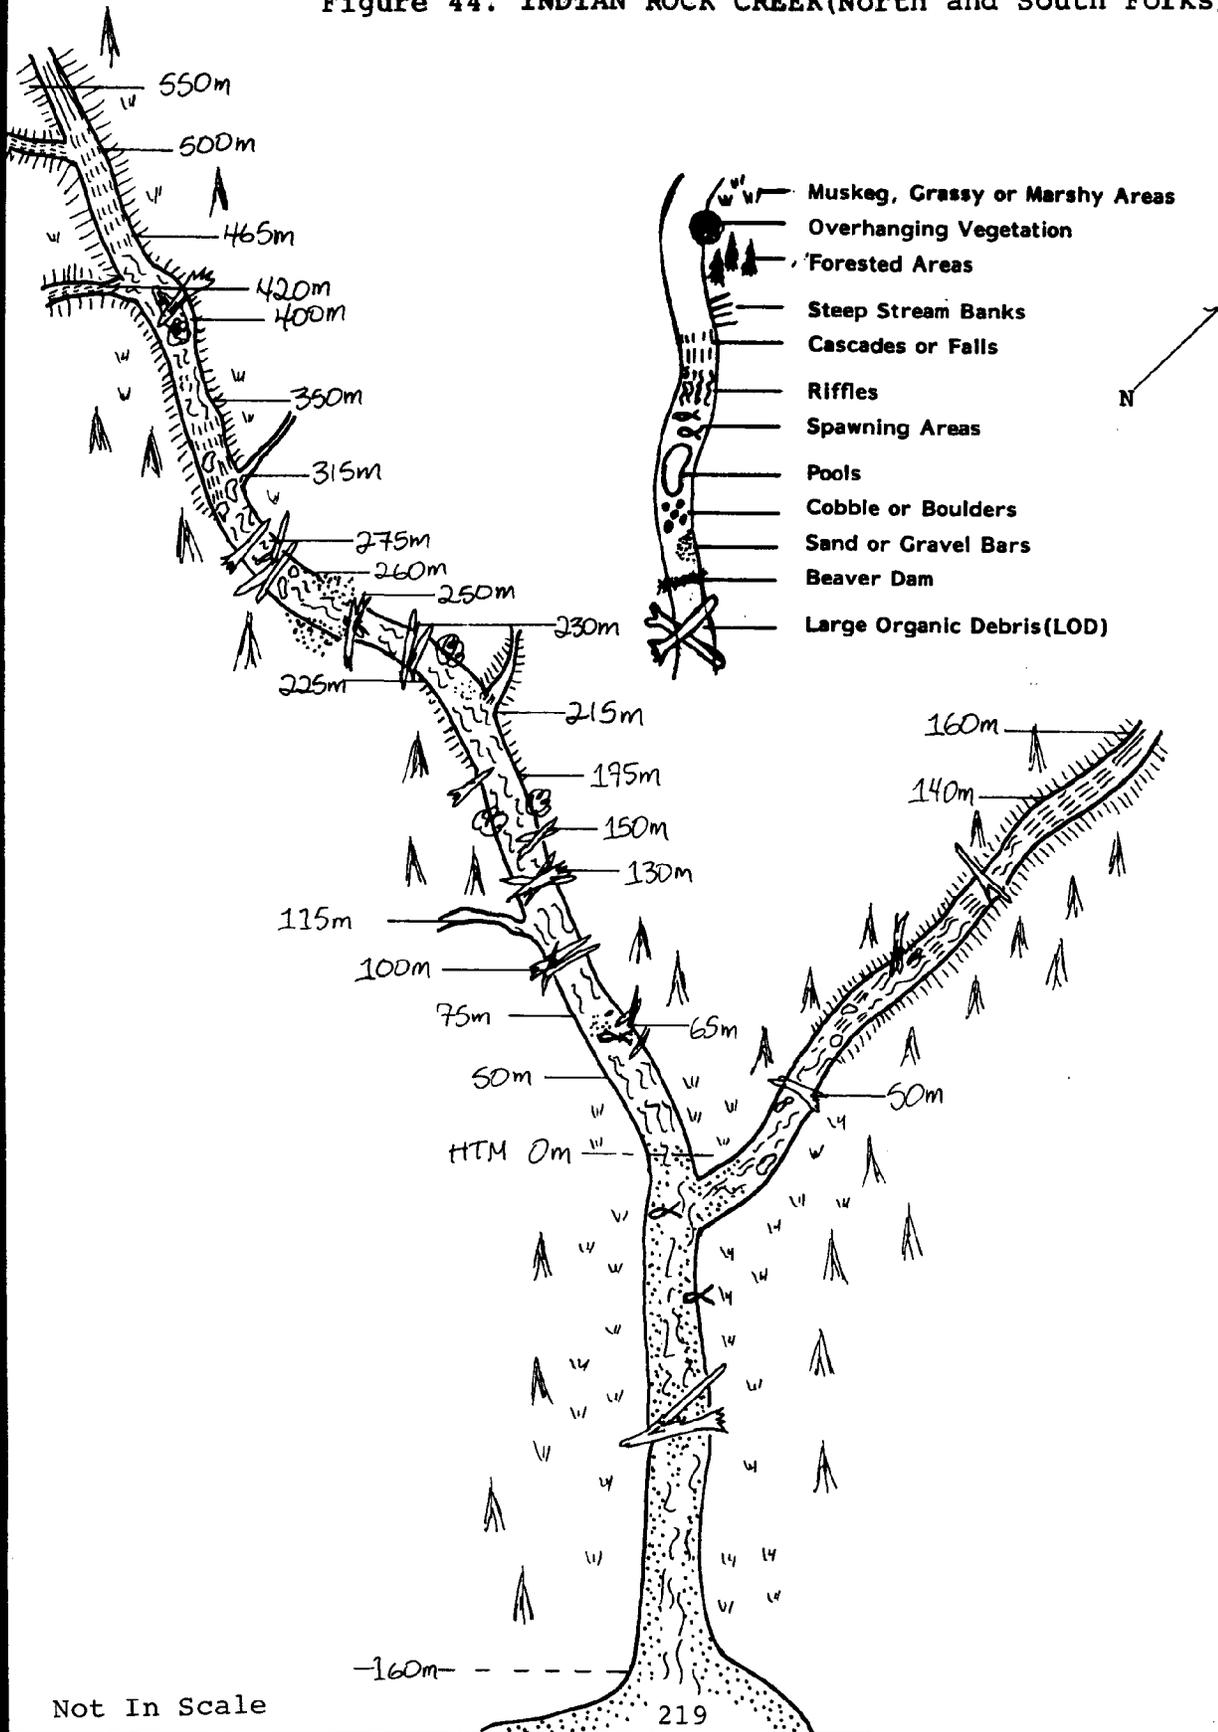

Recommended Escapement

Based on spawning area available and gravel quality, only 175 spawning pairs of pinks could probably utilize this creek.

Potential Production Summary

Due to the marginal gravel quality, only approximately 62 pinks could be expected to return based on a 1.2% egg-fry survival rate and a 2% ocean survival.

Figure 44. INDIAN ROCK CREEK(North and South Forks)

INDIAN ROCK CREEK (North and South Forks) Watershed No. 308-01
 Stat. No. 101-24-083

- 160-0m 5% spawning area intertidally (80m² area); bottom is mostly gravel and clay at mouth, with gravel and rubble prevailing toward High Tide Mark (HTM) at 0m. Stream forks intertidally at 0m.
- 0-50m (North Fork) Riffles
- 140m (North Fork) Series of steep cascades.
- 160m (North Fork) 3.5m falls, a probable barrier.
- 0-50m (South Fork) Salt tolerant sedges and flat banks here.
- 65m (South Fork) Undercut spruce roots with a bottom of mostly cobble.
- 75m (South Fork) 7m² spawning area at pool "tail-out".
- 100m (South Fork) Two logs over channel.
- 115m (South Fork) Trickle tributary comes in.
- 130m (South Fork) LOD jam.
- 150m (South Fork) Small LOD pile.
- 175m (South Fork) 12m² area good spawning riffle.
- 215m (South Fork) Steep tributary enters channel.
- 225m (South Fork) Small south bank slump.
- 230m (South Fork) Two logs across creek.
- 250m (South Fork) Debris jam - clay banks to 260m.
- 275m (South Fork) Stream stepped over LOD and rock; predominately cobble and rubble bottom, banks are rocky with root tangles.
- 315m (South Fork) Bedrock and boulders at a 5% gradient to 350m; small tributary trickles in.
- 350m (South Fork) Begin cobble and rubble bottom; rocky banks with some muskeg; below 350m, banks are heavily overgrown with moss and ferns.
- 400m (South Fork) Root tangles from large live trees in channel (creek moves around a bit).
- 420m (South Fork) Tributary cascades in (steep) - no spawning or rearing habitat.
- 465m-500m (South Fork) Cascades, 5% gradient bedrock channel.
- 500m (South Fork) 1.5 cfs flow tributary with impassable falls. 40m above mouth (no spawning or rearing).
- 550m (South Fork) 10m barrier falls.
- Spawning Area: Limited
- Intertidal Approximately 80m² area
- Above HTM Approximately 20m² area

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Beaver Creek	101-24-086	306-01
Stream	Number	Geocode
Flow NW into Kwain Slough, .5 mi long./ and muskeg run-off./ flats and gently sloping hillsides. (3.4mi ²)		
Location	Origin	Watershed Type
6/13/81	Falls up East Fork - none in East Fork.	in area).
620m above mouth		
Date Surveyed	Barriers	Stage
2% above dams		
5% in forks	.5 fps above dams	1.5m (above dams)/-
Ave. Gradient	Ave. Velocity/Range	Ave. Width/Range
Flow / Range		
Extensive LOD influence with grassy and woody banks - flooding due to beaver dams - otherwise stable channel.		
Streambank Composition	Stability	Tributaries
		This creek is a fork of Kwain Creek. it forks at 530m above mouth.

Water Quality

At mouth	15.0C	12.0C	--	Clear / None	Amber	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO₂
--	--	--	--	--	--	--	--
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

Above beaver dams: 35% gravel, 15% rubble, 5% boulder, 20% cobble, 10% pebble, 10% sand, 5% silt, 5% organic matter (OM). In beaver ponds, mainly mud and OM. Some occurs, but not bad.

14 obvious redds were spotted, 250m² total area is available; 225m² of it below the lowest beaver dam.

Spawning Area Available Above High Tide Mark (HTM)
(More may be available in unsurveyed section of West Fork).

Not applicable (covered in Kwain Creek Survey).
Intertidal Spawning Area

Rearing Area Beaver ponds and LOD pools abundant. p:r = 3:1 - excellent for coho.

See stream maps.	--
Pool/Riffle Frequency (P:R-Ratio)	Ave. Pool Depth/Range
Extensive cover available from heavy LOD load, undercut banks, deep pools and debris from beaver activity.	

Available Cover
Abundant: Dipterans, trichopterans, and some ephemeropterans (ponds full of tadpoles).
Aquatic Invertebrates/Available Food Source

Moderate amount of algae occurs on rocks.
Aquatic Vegetation
Lower creek - grasses and sedges, in upper creek, dense currant, berries, devil's club under alder, cedar, hemlock and spruce canopy.

Terrestrial Vegetation
80% from topography, some riparian vegetation and forest vegetation.

Shading
Excellent, this creek probably has the most extensive (considering creek size) and best quality rearing

Extent and Quality of Rearing Area
area of any creek on the Island - due to heavy cover, low gradient and channel braiding (alot is available above and below the dams).

Reported and Suspected Use of Stream by Fish and Fishermen
Coho utilize entire creek, pink and chum use mainly the lower end.

Use by Fish
No known fishing occurs.

Use by Fishermen

Wildlife Present
Heaviest beaver influence on creek observed on Annette.

Comments and Recommendations
This creek produces 2000+ coho smolts annually and should be protected and managed as a major coho stream. Do not disturb beaver dams and check dams for passability annually.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/13/81	Coho	Fry	Over 150	below first dam!	Two or three thousand could rear in this creek.
9/21/81	Pink	Adults	-	6	On-foot Count

Survey(s) and Dates Conducted

C. Huntington, 6/13/81

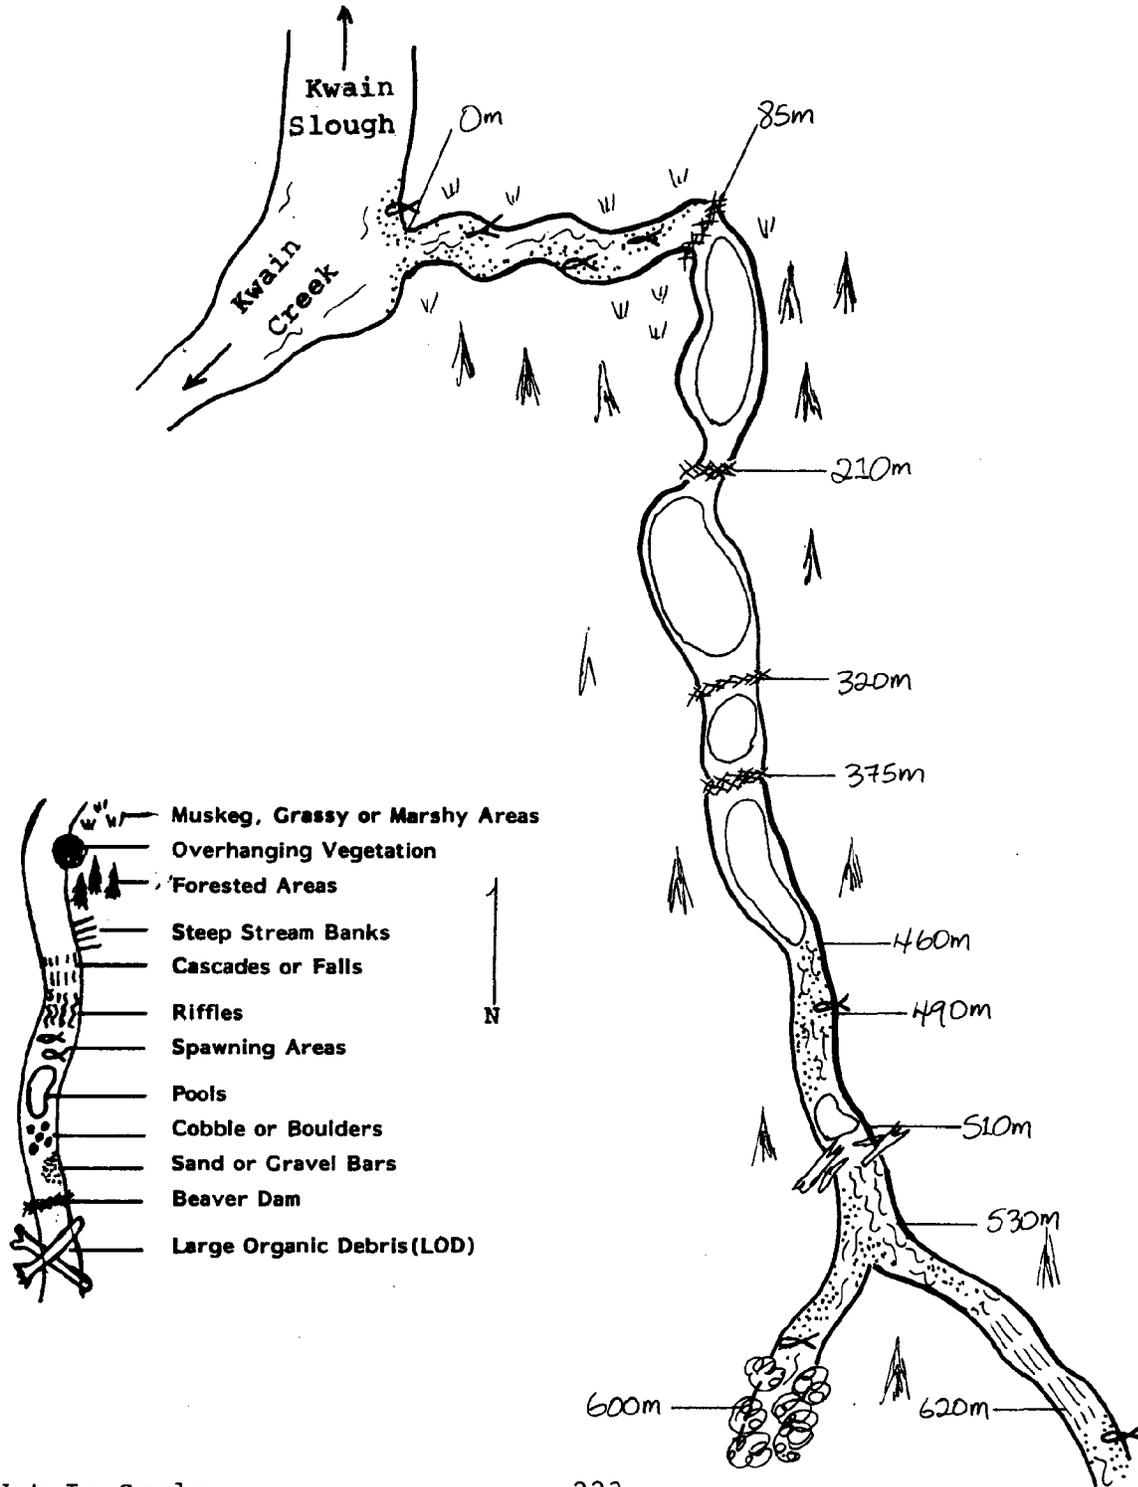

Recommended Escapement

Based on the available spawning area (including unsurveyed area in the upper west fork) and extensive rearing area, recommended escapements are 375 pink, 25 chum, and 18 coho spawning pairs.

Potential Production Summary

Gravel quality is fair, so a 10% egg-fry survival rate will be assumed. Production potential from Beaver Creek is 1115 pinks, 125 chums and 102 coho returning to Annette Island.

Figure 45. BEAVER CREEK

Not In Scale

BEAVER CREEK

Watershed No. 306-01
Stat. No. 101-24-086

- 0m Mouth, where Beaver Creek flows into Kwain Bay Slough.
- 0-85m 225m² spawning area below first beaver dam at 85m; .2m high beaver dam passable at high flow, 30 x 110m pond about 2.5m maximum depth (3600m² rearing area).
- 210m Second beaver dam passable at high flow, 20 x 110m pond, 2m maximum depth (2200m² rearing area).
- 320m Third dam passable at high flow, 55 x 30m pond, 2m maximum depth (1650m² rearing area).
- 375m Fourth dam passable at high flow, 30 x 85m pond, 1.5m maximum depth (2550m² rearing area).
- 460m Uppermost end of beaver dams and ponds.
- 490m Two old redds here.
- 510m 20 x 10m pool formed by old dam.
- 460-530m Average Stream Width (ASW) = 1.5m, Average Stream Depth (ASD) = .20m, 35% gravels (26m² spawning area); stream forks at 530m.
- 530-600m (West Fork)
Channel is extremely choked with riparian vegetation, although spawning could occur above thicket (it is passable).
- 530-620m (East Fork)
Barrier at long, steep cascade in bedrock - some good gravels above this, but no fry observed.
- Spawning Area: Total area is approximately 250m², mainly above HTM, however, in lower 225m², there may be some salt water influence.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Kwain Creek

101-24-087

306-02

			Resistivity = 47,169 ohms/cm ³
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall

Spawning Area

Intertidally: 10% silt, 20% sand, 10% pebbles, 55% gravels, 5% cobbles. Below Falls: 5% bedrock, 20%

Overall Stream Bottom Composition

boulders, 25% rubble, 30% cobble, 10% gravel, 5% pebbles, 5% sand and fines. Falls to 350m: 2% cobble, 55% gravel, 8% pebbles, 20% sand, 10% silt. Above 350m: 25% rubble, / Some occurs with presence of fines. 55% cobble, 15% gravel, 5% pebbles.

Gravel Compaction

10m² - limited area below falls; above falls - extensive spawning habitat occurs between

Spawning Area Available Above High Tide Mark (HTM)

150-300m; 500m² fair quality, 200m² good quality and 100m² excellent quality - totalling 800m² potential area.

By low-level aerial photography: 3250m² area available (3450m² fair quality area estimated by conventional Intertidal Spawning Area survey technique).

Rearing Area Overall p:r = 1:2, pools

created by LOD, bends in creek and root tangles./

Above falls .30m/ up to

Below falls .25m/ .75m

--

--

Pool/Riffle Frequency (P:R Ratio)

Intertidally - some undercut banks are available.

Ave. Pool Depth/Range

Above HTM, overhanging vegetation,

Ave. Pool Size/Range

LOD and root tangles provide a moderate amount.

Available Cover

Abundant intertidally: amphipods and isopods. Above HTM: fairly abundant; predominately ephemeroptera.

Aquatic Invertebrates/Available Food Source

Sparse - some filamentous algae occurs.

Aquatic Vegetation

Devil's club, salmonberry, and timber (spruce and hemlock) above HTM. Sedges, grasses, and herbs intertidally.

Terrestrial Vegetation

Less than 5% below HTM. 90% to barrier, 25% above barrier to forks, 90% above forks.

Shading

Some exists intertidally for pink and chum fry; limited coho habitat except above the barrier falls

Extent and Quality of Rearing Area

where a moderate amount occurs. Most area is suited best for pink and chum.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, coho and cutthroat currently utilize this creek.

Use by Fish

Some subsistence fishing and hunting occurs.

Use by Fishermen

Wildlife Present

Beaver activity and mink observed.

Comments and Recommendations

Currently there is extensive spawning area available for pink and chum, the creek being one of the major producers of salmon. However, more area could be opened by putting in a fish passage (modifying the barrier cascades at 125m) - the rearing area above the falls may be the limiting factor to coho production.

A benefit:cost analysis would be desirable.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
Escapement records sine 1955: ADF&G and USFWS Report that up to 25-50,000 fish have been observed in this creek.					
6/12/72	Pink	Fry	Not counted		
1974	Pink	Adults	1522	--	USFWS Estimated Total Escapement
1975	Pink	Adults	12,486	--	USFWS Estimated Total Escapement
1976	Pink	Adults	5888	--	USFWS Estimated Total Escapement
8/5/80	Coho	Fry	50	--	Water temperature recorded at 20C!
	Cutthroat	Fry	25	--

9/7/80	Pinks mainly (mixed)	Adults	6000	--	Aerial count - seen in slough.
9/1/81	Pinks mainly (mixed)	Adults	300-400	In slough	
			100-200	- In ball below creek mouth	Aerial count
9/26/81	Pink		1279	358	On-foot Count
	Chum		0	1	On-foot Count

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, J. Yuska, 6/13/81 and USFWS, 6/21/72

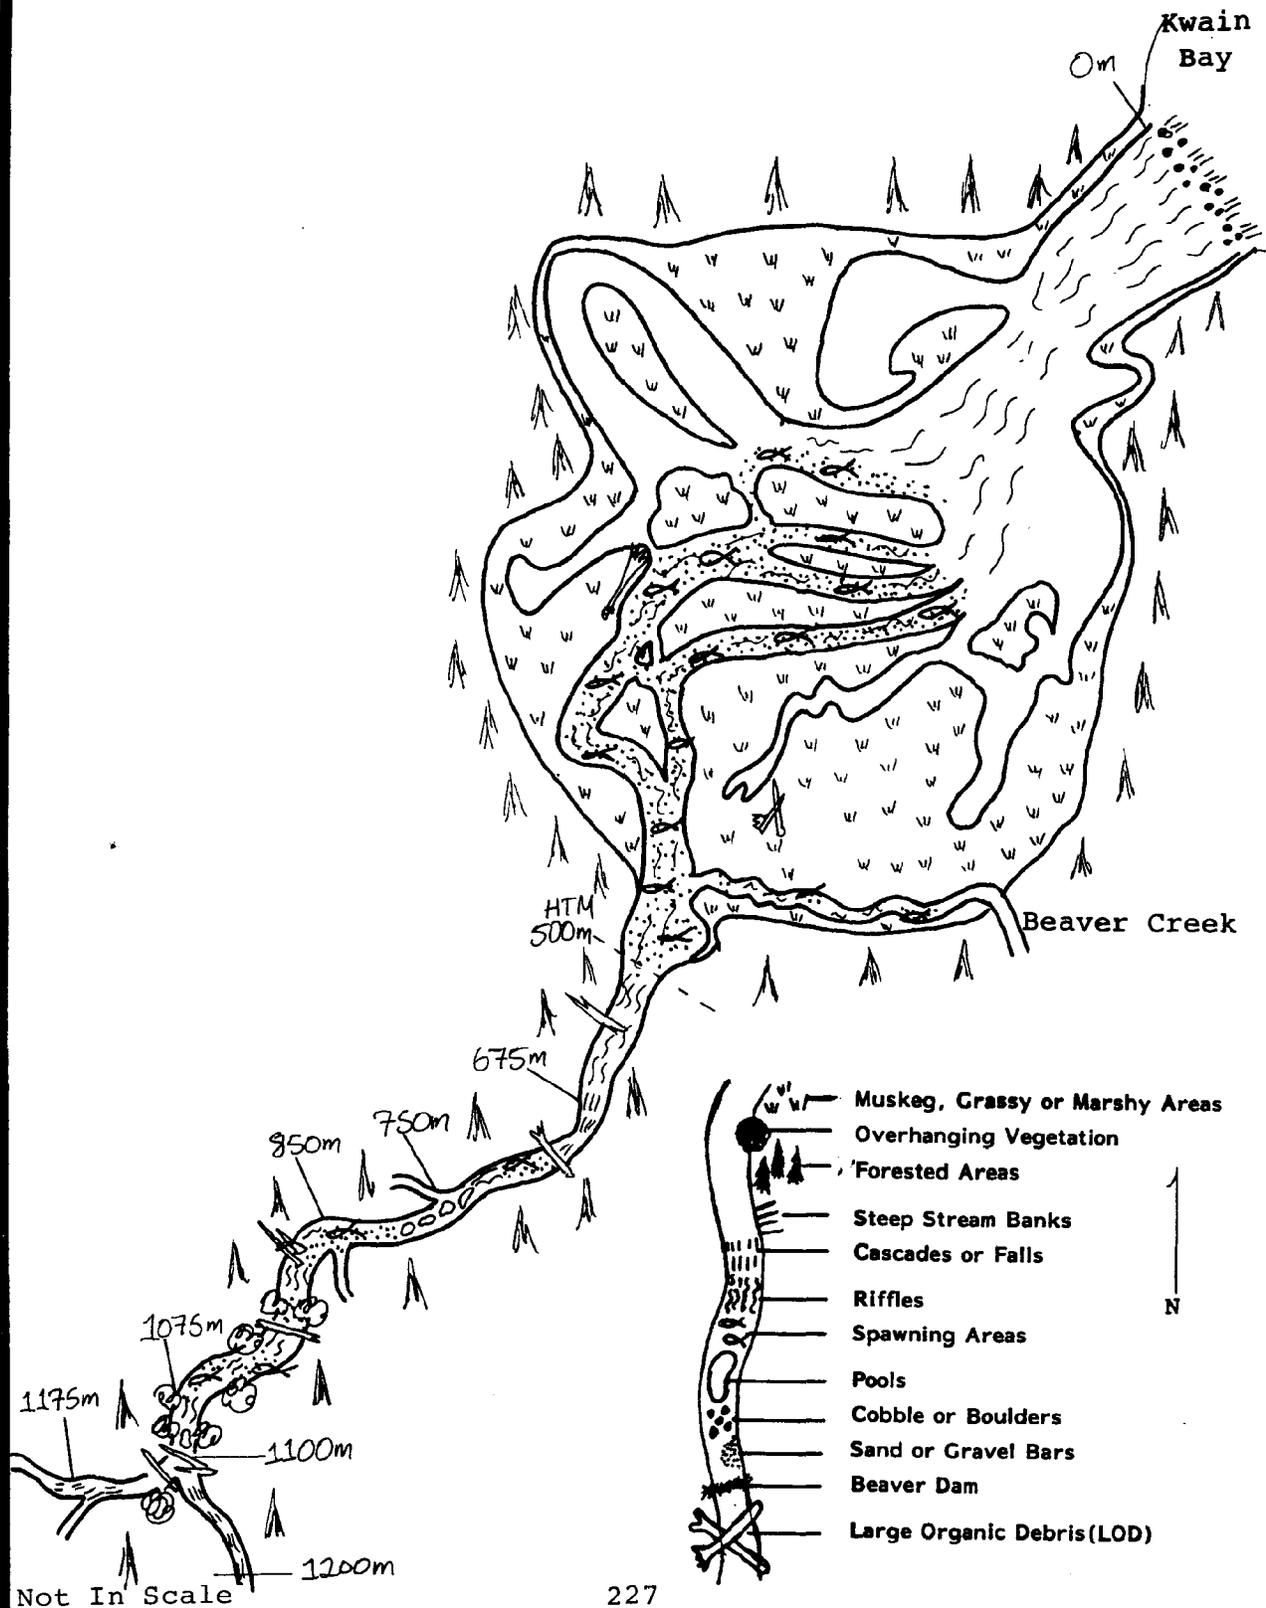

Recommended Escapement

Using the estimate of spawning area estimated by low-level aerial photography and computed spawning area available recommended escapements are 5420 pink and 355 chum spawning pairs. Coho probably do not utilize this fork.

Potential Production Summary

Based on a 10% egg-fry survival rate due to the fair gravel quality, potential returns to Annette Island from Kwain Creek are 16,100 pinks and 1750 chum. Coho fry spotted in this creek are probably overflows from Beaver Creek. However, much potential coho spawning and rearing habitat occurs above the barrier falls with a 68 coho spawning pair and 400 coho adult return production potential.

Figure 46. KWAIN SLOUGH AND CREEK

KWAIN BAY SLOUGH AND KWAIN CREEK

Watershed No. 306-02
Stat. No. 101-24-087

- 0m Mouth of creek is bedrock, boulder cascade flowing in-
to Kwain Bay. Just above 0m, creek is very wide and
slow flowing (too slow for spawning). Spawning
area begins where creek narrows into channels.
- 500m High Tide Mark (HTM), intertidal spawning area
flows through an open, grassy (sedges, forbes, and
rushes) slough.
- 500-675m Cobble, boulder riffle (10m² spawning area); at
675m is a 1.5m steep (40° rise) falls over bedrock,
a probable barrier to salmon.
- 750m Tributary enters with good coho rearing area to
60m (.5 cfs flow).
- 850m .5 cfs flow tributary enters in; the best spawning
area in creek occurs from this point, downstream
to the upper end of the falls at 675m.
- 1075m Upper limit of good spawning area.
- 1100m Heavy LOD and overhanging vegetation - stream bottom
mostly rubble and cobble; stream forks.
- 1200m (East Fork) 3m chute and cascades (barrier). End of survey.
- 1175m (West Fork) Stream splits again - one tributary has a 2m
falls with no plunge pool, and a cascade on the main
channel poses a definite barrier. End of survey.

Spawning Area:

Intertidal (majority of area available)			
	0-500m	3450m ²	Total Area
Above HTM	500-675m	10m ²	Current Available
Above barrier at	675m	800m ²	Potential Area

(3520m² Area Available Intertidally, Estimated by Low-Level
Aerial Photography)

Spawning Area

Intertidally: boulders, cobble and sand in lower end of slough, in channels, pebbles and small gravels

Overall Stream Bottom Composition
 (increasing in size up slough) prevail. Above HTM: gravels mixed in/ Some due to silt and sand
 with cobble, cobble, boulder and eventually bedrock. intertidally - none above HTM.
 Gravel Compaction

Gravel size increases with cobble, but is still good. Most gravels occur below 2000m, 9610m² total

Spawning Area Available Above High Tide Mark (HTM)

available. (Many gravel bars occur and may indicate flashiness).

An immense amount of area is available. By low-level aerial photography: 12,000m² area (approximately 15,000m² estimated by conventional survey techniques).

Intertidal Spawning Area

Rearing Area

Some pools intertidally; however, they are sparse. -- -- -- --

Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range

Undercut banks are only cover intertidally. LOD and undercut banks occur above HTM.

Available Cover

Abundant intertidally: isopods and amphipods are common. Moderately abundant above HTM: simuliids (blackflies)
Aquatic Invertebrates/Available Food Source are common.

Algae (brown periphyton) common and some marine algae intertidally. Moss occurs on rocks above HTM.

Aquatic Vegetation

Sedge, grasses and herbs intertidally. Above HTM is berries, alder and hemlock spruce and cedar canopy.

Terrestrial Vegetation

0% intertidally. 40% above HTM mainly due to canopy.

Shading

Many coho fry seen in a moderate amount of rearing area. Intertidally - some occurs in undercut banks

Extent and Quality of Rearing Area

for pink and chum fry (abundant food exists).

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, coho and cutthroat utilize creek (rainbow in Purple Lake).

Use by Fish

Light subsistence fishing recorded and some hunting.

Use by Fishermen

Wildlife Present

Deer, wolves, mink and marten have been observed. Canada Geese feed in the slough.

Comments and Recommendations

Excellent pink and chum spawning grounds and extensive freshwater rearing and spawning habitat for coho
 make this creek one of the top two producers of salmon on Annette Island. No habitat improvement is
 recommended; trying to make lower or upper Purple Lake available would require more than one fish
 passage, although it could be stocked with excess fry for rearing and a benefit cost study would be
 desirable.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
10/14/71	Pink and Chum	Adult	30,000	approximately	Varies from 25-50,000 - USFWS Estimate

9/1/81	Pinks Mainly	(mixed) - Adults	300-400	--	Aerial Count - fish counted in slough - many uncounted carcasses seen.
9/21/81	Pinks	Adults	12,800	134	On-foot Count Peak
	Chum	Adults	42	65	On-foot Count Peak

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, J. Yuska, 6/13-14/81 and USFWS, 10/14/71, 8/1/72

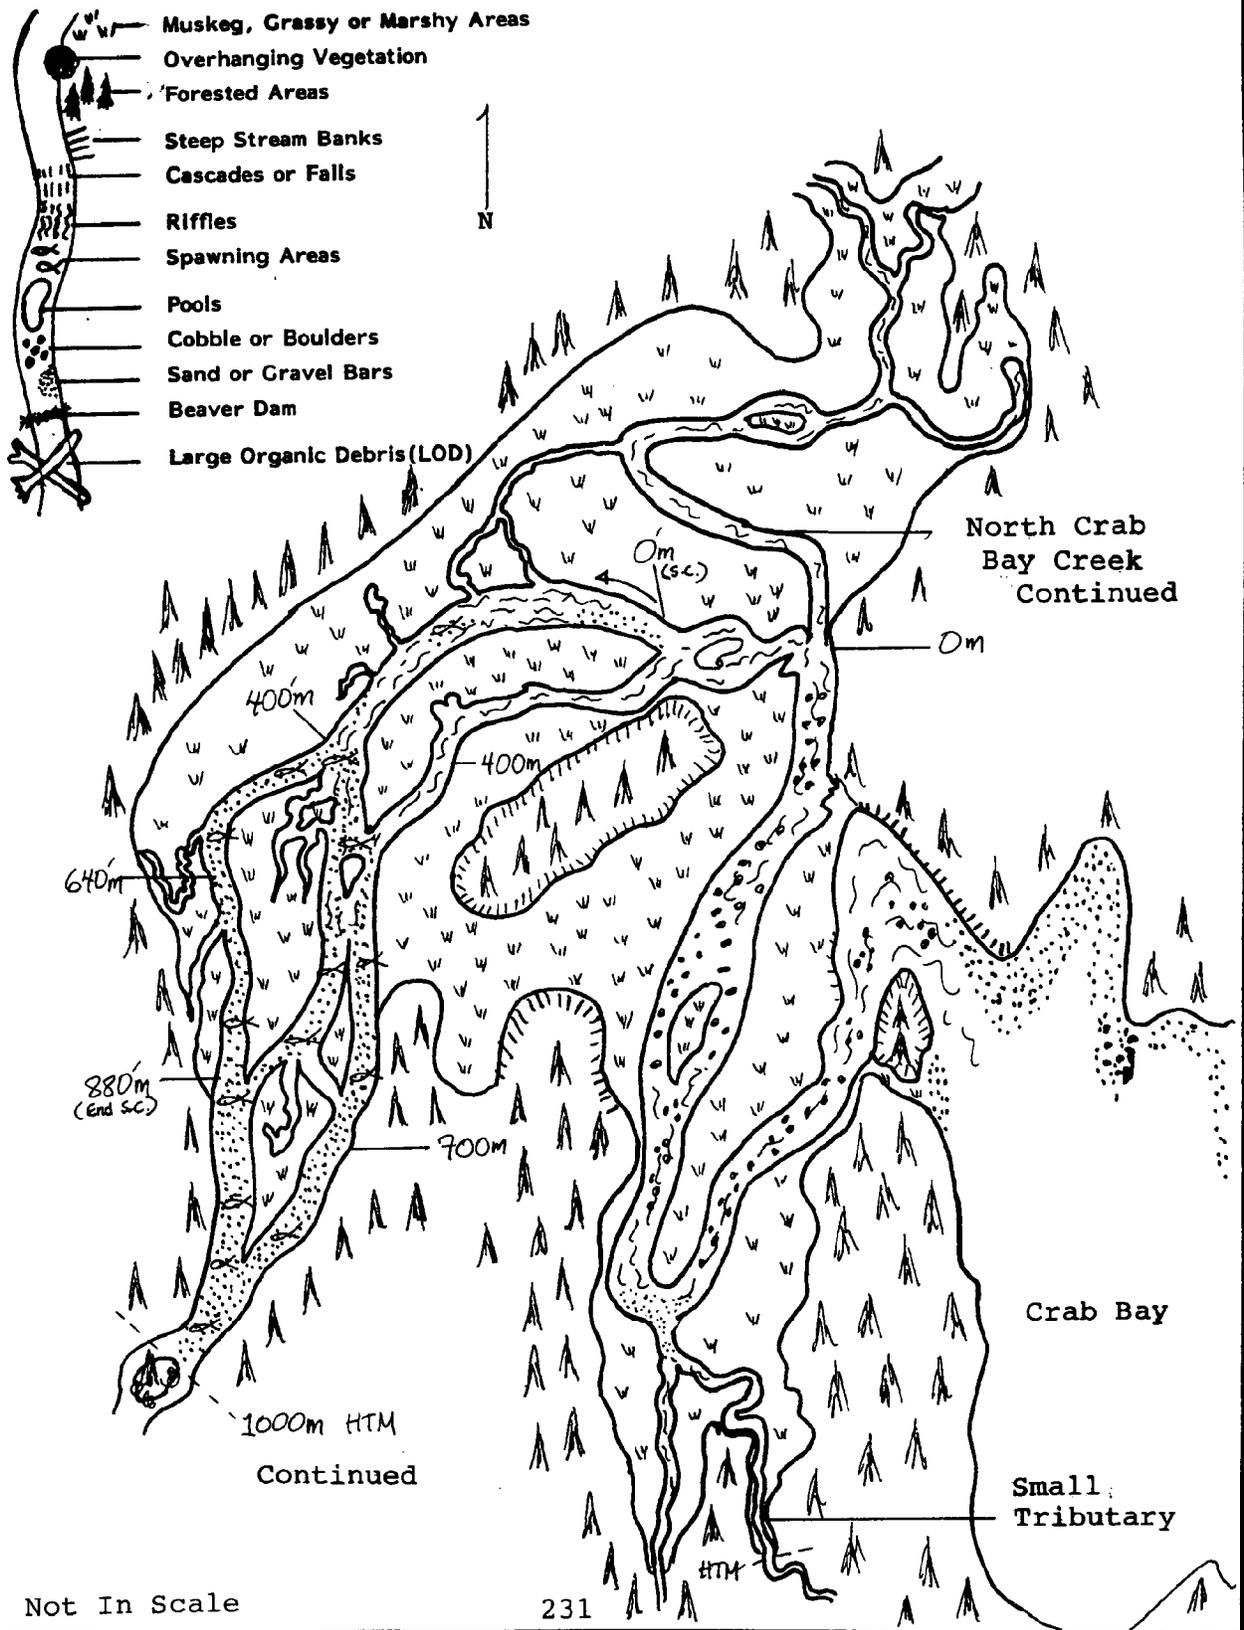

Recommended Escapement

Based on the spawning area estimated by low-level aerial photography and conventional survey technique and on historical escapements, recommended escapements are: 6500 pink (that will be very site-selective) and 390 chum spawning pairs intertidally. In the freshwater section of the creek, spawning area is available for another 6000 pink, 240 chum and rearing area for 25 coho spawning pairs.

Potential Production Summary

Assuming an overall egg-fry survival rate of 10%, potential production is 37,125 pinks, 3120 chums and 141 coho returning to Annette Island. Most of these fish are probably intercepted in Seine and Gillnet fisheries around the Island.

Figure 47. CRAB BAY SLOUGH AND SOUTH CRAB CREEK

Not In Scale

SOUTH CRAB CREEK

Watershed No. 305-01
Stat. No. 101-24-094

0m Point at which North Crab Creek splits off; no spawning areas below this point intertidally (channel below 0m is mainly boulder and cobble). Small tributary entering main channel on south end of the slough is 200m long from High Tide Mark (HTM), has a .5 cfs flow and about 3-10m² spawning area.

0-400m (South Channel)
No usable gravel here.

400-700m Average Stream Width (ASW) = 18m, Average Stream Depth (ASD) = .3m, 30% spawning gravels (1620m² spawning area).

700-100m ASW = 36m, ASD = .1m, 90% spawning gravels (9720m² spawning area). HTM at 1000m. (Continued, second section.)

0-400m (North Channel)
ASW = 11-12m; bottom composition 70% spawning gravel, mixed with pebbles and some mud (3080m² spawning area).

400-600m Gravels become finer with sand, mud and shell, and is no longer good for spawning.

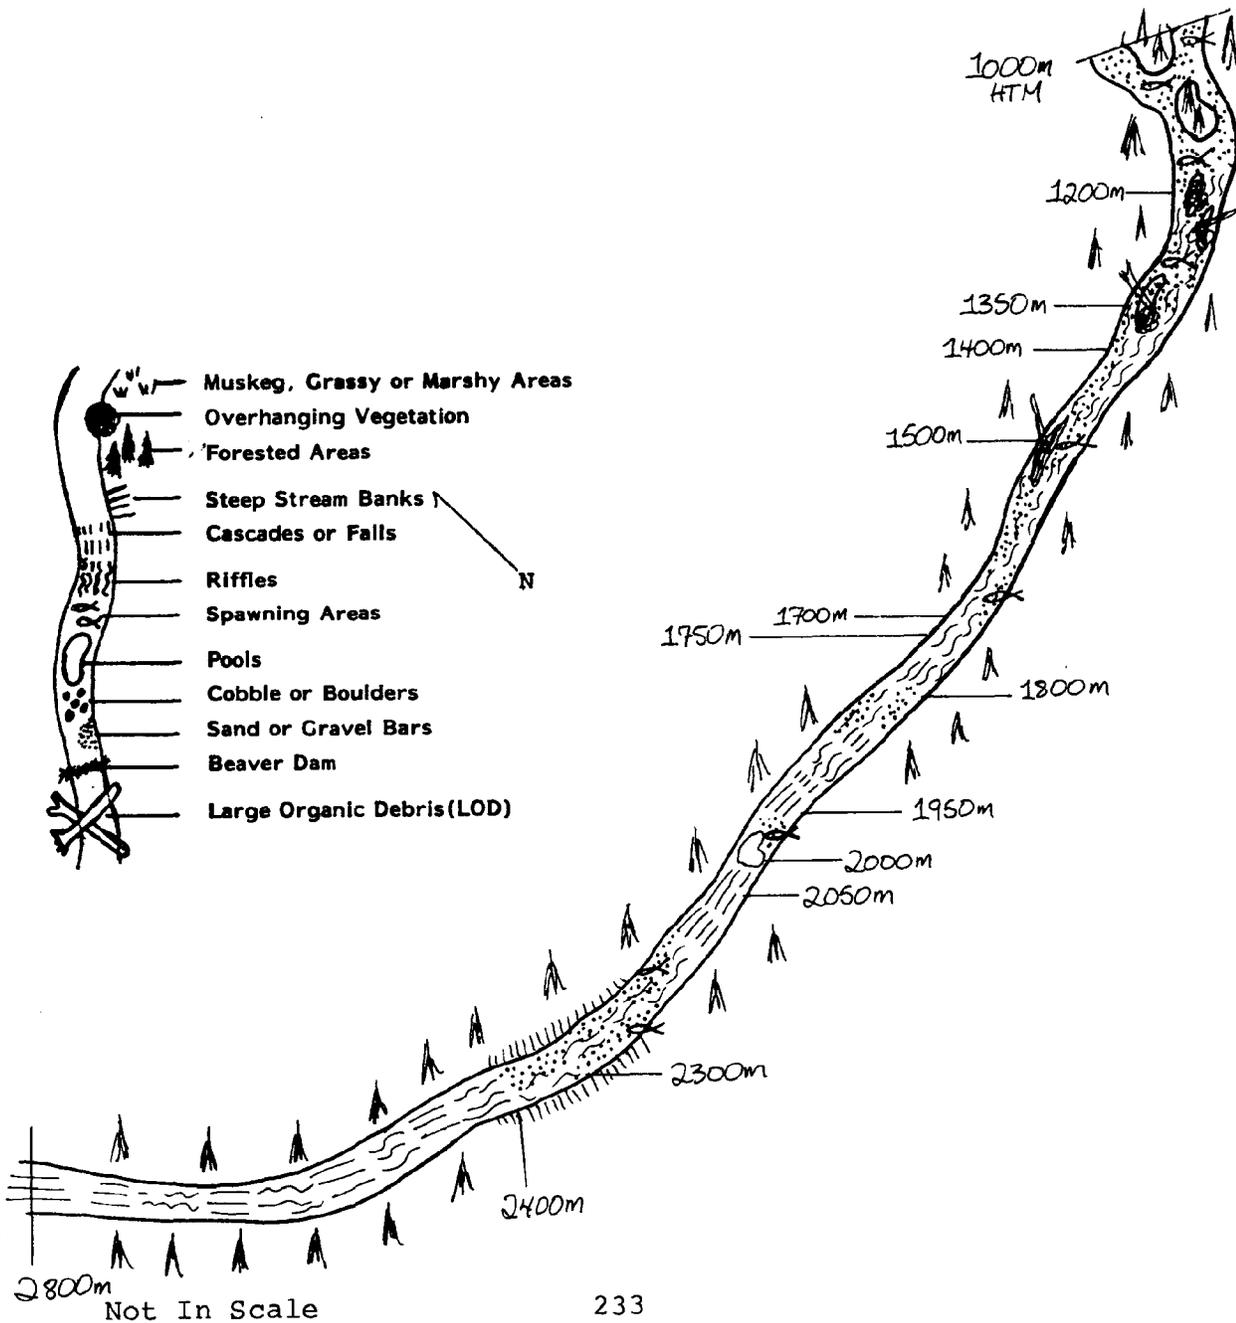

400-880m 10% spawning gravels (624m² spawning area).

Spawning Area: Intertidal area is 15,044m² spawning area in slough, 3-10m² in small tributary.

12,000m² area available
Estimated by Low-Level
Aerial Photography

(CONTINUED,
SECOND SECTION)

Figure 48. SOUTH CRAB CREEK

Not In Scale

SOUTH CRAB CREEK (CONTINUED)

1000-1200m HTM, ASW = 40m, ASD = .08m, 90% spawning gravels (7200m² spawning area).

1200-1350m ASW = 15m, ASD = .1m, large cobble present, but still 50% spawning gravels (1125m² spawning area).

1350-1400m ASW = 15m, bottom composition: 30% gravels, 50% cobbles, 30% small boulders (150m² spawning area).

1400-1500m ASW = 17m, ASD = .1m, 20% spawning gravels (170m² spawning area), some undercut banks.

1500-1700m ASW = 8m, ASD = 6m, bottom has alot of boulders with 20% spawning gravels (560m² spawning area).

1750-1800m Bedrock riffle; trees make up majority of riparian vegetation.

1950-2000m Bedrock riffle with a spawning area at 2000m.

2050m Waterfall 1.5m high, all bedrock, but not a barrier.

2300m 40 ft high banks (like a gorge) over creek; bottom has 4 and 5m gravel bars, making bottom 20% spawning gravels (180m² spawning area).

2400-2800m Less than 1% usable spawning gravels, bottom all bedrock with an 8m barrier falls at 2800m.

Spawning Area: Above HTM 9610m² spawning area total

ANNETTE ISLANDS STREAM SURVEY SUMMARY

North Crab Bay Creek 101-24-095 305-02
 Stream Number Geocode Forested and exposed granite
 Flows SE into Crab Bay, .8 mi long. Mountain slope run-off and springs. / slopes and alpine valleys.
 Location 1250m from mouth Origin Falls and flows in sandstone at 1250m. Watershed Type 70mi² in area.
 6/13/81 to barrier. sandstone at 1250m. Low flow +2 ft
 Date Surveyed Section Surveyed Barriers Stage Flood Height
 Low (1-2%) 1.5 cfs / -- .2-1 fps / -- 9m / -- .08m / --
 Ave. Gradient Flow / Range Ave. Velocity/Range Ave. Width/Range Ave. Depth/Range
 Sand, mud and clay with grasses and sandstone
 upper end. / Some active undercutting but generally stable. This creek is a fork of South Crab
 Streambank Composition / Stability Tributaries Creek - it has one tributary.

Water Quality

(12.0C in upper end)
 Intertidally 13.3C 17.0C 5.5 Clear / Slight Light Amber -- --
 Sample Site Temp.-Air Temp.-Water Ph Clarity/Turbidity Color D.O. CO₂
 -- -- -- Water probably gets very silty during heavy rains.
 Total Alkalinity Total Hardness Dissolved Solids Other/Overall

Spawning Area

In lower sections: silt, clay and sand predominate. Some small gravel occur farther up - gravels of
 Overall Stream Bottom Composition Moderate compaction due to
 marginal quality for spawning. heavy accumulation of fines.
 Gravel Compaction

Only 50m² occurs above HTM and this is of marginal quality.
 Spawning Area Available Above High Tide Mark (HTM)

Approximately 560m² of poor - marginal quality area, only suitable for pinks, occurs.
 Intertidal Spawning Area

Rearing Area

Very few pools. -- -- -- --
 Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range
 Some cover available in undercut banks and LOD over 1100m - limited.
 Available Cover
 Amphipods and isopods are numerous intertidally. Scarce above HTM.
 Aquatic Invertebrates/Available Food Source
 Some brown periphyton, marine algae and mosses.
 Aquatic Vegetation
 Mainly estuarine - sedges, grasses and herbs. Wooded area begins above 1100m.
 Terrestrial Vegetation
 0% in lower section, 10-20% above 1100m.
 Shading
 Some rearing area occurs intertidally because of undercuts, LOD and low velocity and gradient. Limited
 Extent and Quality of Rearing Area
 above 1100m.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink and chum utilize creek if at all (and these are probably overflow from South Crab Creek). Coho may
 Use by Fish use, but not extensively.
 No fishing known.
 Use by Fishermen

Wildlife Present

See South Crab Bay Slough.

Comments and Recommendations

This is mainly a pink and chum stream; however, coho may use some of the upper gravels (or fry may just
 wind up here after flooding or competition for space occurs in South Crab Creek). This creek produces
 small numbers of salmon because of marginal quality spawning areas and limited rearing areas.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
Most counts previously were combined with South Crab Bay Creek's counts.					
6/13/81	Coho	Fry	A few		
9/21/81	Pinks	Adults	None seen		

Survey(s) and Dates Conducted

J. Yuska, E. Biggs, 6/13/81

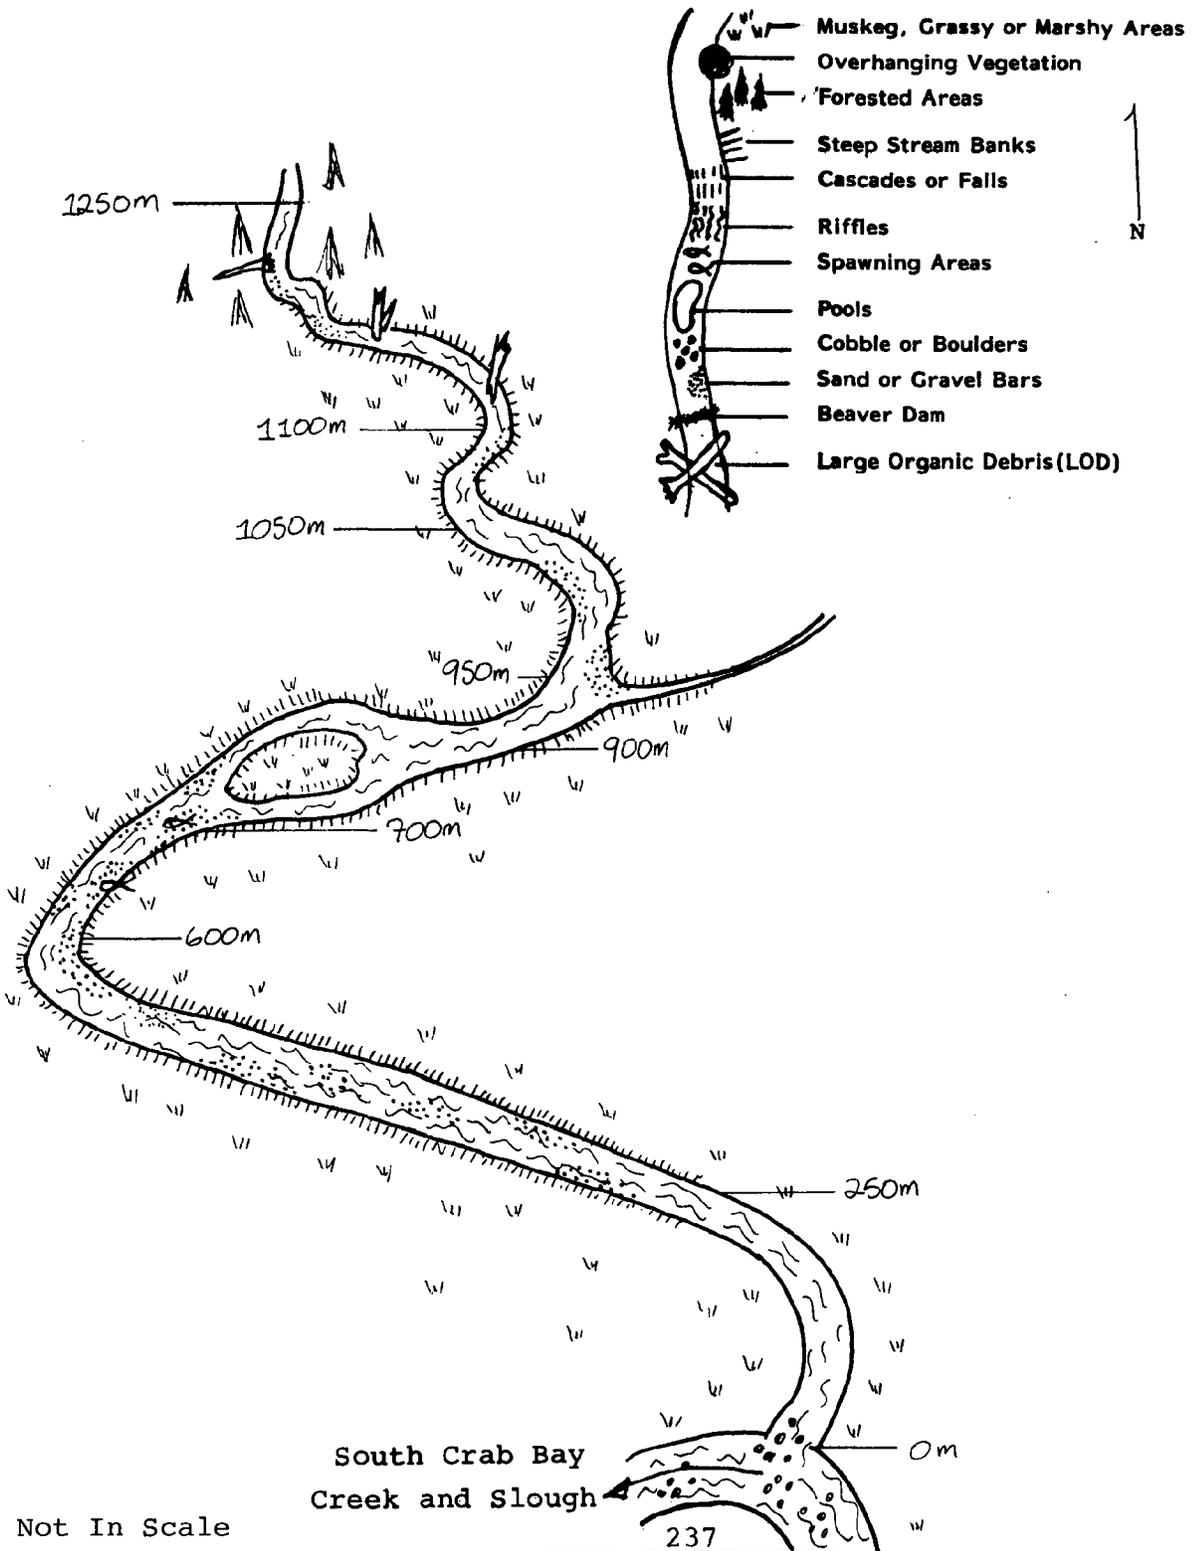

Recommended Escapement

Pink and chum probably only utilize this creek if Crab Bay slough overflows, and even if they did, survival would be low due to the poor gravel quality.

Potential Production Summary

None calculated, too many fines occur in the bottom.

Figure 49. NORTH CRAB BAY CREEK

NORTH CRAB CREEK

Watershed No. 305-02
Stat. No. 101-24-095

- 0m Point where North Crab Creek forks off from Crab Slough.
- 0-250m Average Stream Width (ASW) = 9m; marginal gravels, compact and small.
- 600m Gravels increase in size, but a compact and fine gravels are still present, 10% usable spawning area; ASW = 9m (180m² spawning area).
- 700m Silt covers 30% clay, deposits present, with 20% gravels (180m² spawning area).
- 900m Gravels form a thin layer covering clay, less than 5% usable.
- 950m Tributary enters with 5m² spawning area at mouth.
- 950-1050m Pronounced bank instability.
- 1100m ASW = 7m, ASD = .08m, bank instability increases; still is a high percentage of fine sediment in bottom.
- 1100-1250m Some LOD present; at 1250m, stream ends in a narrow high cascade through a sandstone cave (200m² spawning area).

Spawning Area:

- Intertidal 360m² approximately spawning area
Above HTM 200m² spawning area

ANNETTE ISLANDS STREAM SURVEY SUMMARY

South Blunt Mountain Creek	101-24-096	304-01
Stream Flows NE into Revilla Channel, .4 mi. long.	Number Mountain slope run-off.	Geocode Steep forested and exposed granite slopes.
Location 6/20/81	450m above mouth to barrier.	Origin Falls at 450m.
Date Surveyed	Section Surveyed Moderate to steep, 9 cfs (7/6/76)	Barriers variable
Ave. Gradient	Flow / Range	Ave. Velocity/Range
--	--	--
Streambank Composition	Stability	Tributaries
		One main fork at 60m.

Water Quality Above HTM	12.3C	9.0C	7.0 (7/6/76)	Clear / None	Slight Amber	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO2
--	--	--	--	--	--	--	--
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

Above 250m - all bedrock and boulders. Mainly cobble and boulders with less than 10% gravels.
Overall Stream Bottom Composition
 Intertidally, gravels increase to 50% in areas. Minimal - no fines.
 Stream's flashiness may limit egg survival although some gravel bars exist. Gravel Compaction 133m² area available -
Spawning Area Available Above High Tide Mark (HTM)
 fair quality.
 250m² area available of fair quality spawning gravels.
Intertidal Spawning Area

Rearing Area

Pool/Riffle Frequency (P:R Ratio)	--	--	--
Ave. Pool Depth/Range	--	--	--
Ave. Pool Size/Range	--	--	--

Few pools
 Some LOD occurs and channel braiding.
Available Cover
 Sparse
Aquatic Invertebrates/Available Food Source
 Sparse
Aquatic Vegetation
 Blueberries, salmonberry, devil's club, ferns under a hemlock, spruce and cedar canopy.
Terrestrial Vegetation
 Shading is moderate from banks, overhanging shrubs, and canopy.
Shading
 Limited due to flashiness of creek and limited amount of area. Some is available, however.
Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks and chum are known to spawn here.
Use by Fish
 No fishing known.
Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Not much could be done to enhance this stream for salmon production. The stream's flashiness may limit production by disturbing gravels during incubation.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
7/6/76	None Seen				
6/20/81	None Seen				

Survey(s) and Dates Conducted

J. Yuska, 6/20/81 and USFWS, 7/6/76

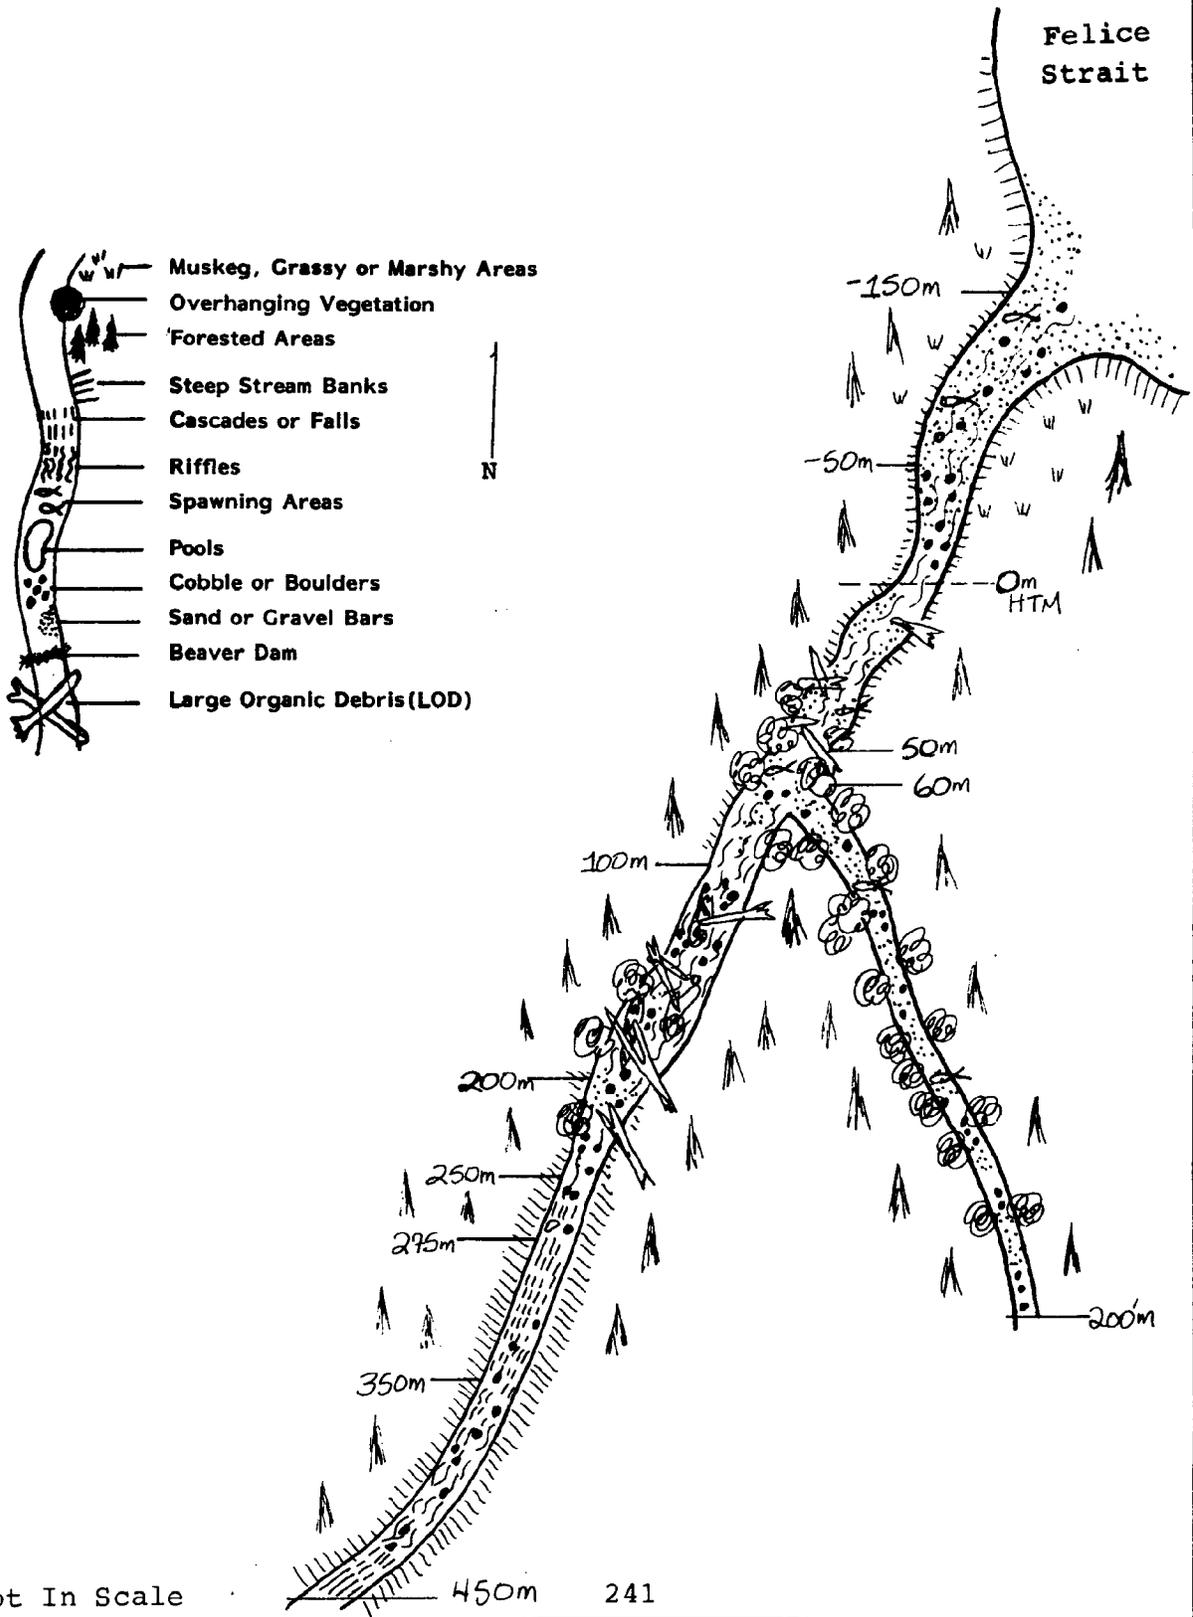

Recommended Escapement

Based on available spawning area, recommended escapement is 510 pink, 45 chum and 10 coho spawning pairs.

Potential Production Summary

Due to creek flashiness, a low in-gravel survival rate 1.2% is assumed. Potential return of adults from this creek is 182 pinks, 28 chum and 8 coho.

Figure 50. SOUTH BLUNT MOUNTAIN CREEK

SOUTH BLUNT MOUNTAIN CREEK

Watershed No. 304-01
Stat. No. 101-24-096

- 150 to -50m Average Stream Width (ASW) = 5m, 50% spawning gravels (250m² spawning area).
- 50-0m No gravels, bottom is all cobbles and boulders. At 0m High Tide Mark (HTM) and here there are 10% gravels, 50% cobble, and 40% small boulders.
- 0-50m ASW = 5m, with 6m wide gravel bars, 10% gravels (55m² spawning area).
- 50-100m ASW = 4m, 10% gravels (20m² spawning area), with alot of LOD in the stream. At 60m, a tributary enters, ASW = 1.5m, with 20% gravels, 50% cobble, 30% boulders; tributary is 200m long at which point gravels become insignificant (60m² spawning area total in tributary).
- 100-200m Gravels are less than 5% of the area, stream banks are unstable, LOD is common and channel braids; bottom is mainly cobble and boulders.
- 200-250m ASW = 3.5m, 10% gravels, 60% boulder, 30% cobble with a moderate gradient (17.5m² spawning area). At 250m, stream enters a steep bedrock and boulder gorge.
- 275m 1.5m falls - may be a barrier to pinks and chums, but coho may be able to traverse it.
- 350m Cascades end, but channel is still moderately steep with less than 5% gravels.
- 450m Gorge ends with a 3m falls, a definite barrier to salmon, little or no spawning gravels above 250m.
- Spawning Area: Intertidal 250m² spawning area
Above HTM 133m² approximately spawning area

Reported and Suspected Use of Stream by Fish and Fishermen

Only trout would use this creek.

Use by Fish

No fishing.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Not much could be done to enhance this creek - little spawning or rearing occurs above falls (USFWS).

Intertidal spawning area is of marginal quality. No fish seen or expected.

Survey(s) and Dates Conducted J. Yuska, 6/20/81, and USFWS 7/6/76

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Camp Cove Creek - Ham Island		101-24-098	300-01	
Stream		Number	Geocode	
Flows NE into Revilla Channel, .5 mi long. Beaver ponds - muskeg run-off.		Forested muskeg area.		
Location	Origin	Watershed Type		
6/20/81	Entire creek - 960m	Beaver ponds at 960m. Low - moderate +1.5 ft		
Date Surveyed	Section Surveyed	Barriers	Stage	Flood Height
1%	4-5 cfs / 2 cfs (5/4/76)	1 fps / to 2 fps	2m / to 1.5m	.2m / up to .5m
Ave. Gradient	Flow / Range	Ave. Velocity/Range	Ave. Width/Range	Ave. Depth/Range
Mainly of soil and rock heavily vegetated with grass and shrubs - some flashiness, but stable channel due to vegetation. Some LOD influence. / 3 small ones (muskeg drainage). Streambank Composition / Stability Tributaries				

Water Quality

--	10.5C	13.0C	--	Clear / None	Light Amber	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO₂
--	--	--	--	--	--	--	--
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

10% bedrock and boulders, 10% cobble and rubble, 30% gravels, 20% pebbles, 20% sand, 10% mud and silt.
Overall Stream Bottom Composition
Some organic matter occurs, mixed in with other sediments. Moderate due to fines present.

Evidence of redds was observed - gravels are patchy mainly occurring in gravel bars - approximately 186m²
Spawning Area Available Above High Tide Mark (HTM)
area exists, however.

30% gravels in a 64m usable stretch - creates 50m² available area.

Intertidal Spawning Area

Rearing Area Many pools of variable size occur formed by boulders, LOD and root wads. .25m / .5m 1m diameter/ up to 3m
Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range
Abundant cover under overhanging vegetation, LOD, root wads, and undercut banks (deep in places).

Available Cover

Scarce

Aquatic Invertebrates/Available Food Source

Alot of aquatic moss occurs.

Aquatic Vegetation

Upper and lower ends - grasses and sedges under trees predominates. In the mid-section, berries and alder are common.

Terrestrial Vegetation

20% in lower and upper end due to canopy. 90% in the middle due to riparian vegetation, topography and

Shading

canopy.

Extensive rearing area occurs in this creek because of extensive cover, low velocity and low gradient.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks utilize creek; chum, coho, cutthroat and Dolly Varden possibly use it also.

Use by Fish

No fishing or hunting known.

Use by Fishermen

Wildlife Present

Beaver activity.

Comments and Recommendations

This creek does not produce alot of salmon, but it has good quality spawning and rearing areas. It could produce alot of trout. Some flashiness may occur - affecting egg and alevin survival; however, affect is unknown at this time.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
5/4/76	Pink	Fry		Not counted	Cutthroat and Dolly Varden could utilize creek also.
6/20/81	None seen				

Survey(s) and Dates Conducted

E. Biggs 6/20/81 and USFWS 7/4/76

Recommended Escapement

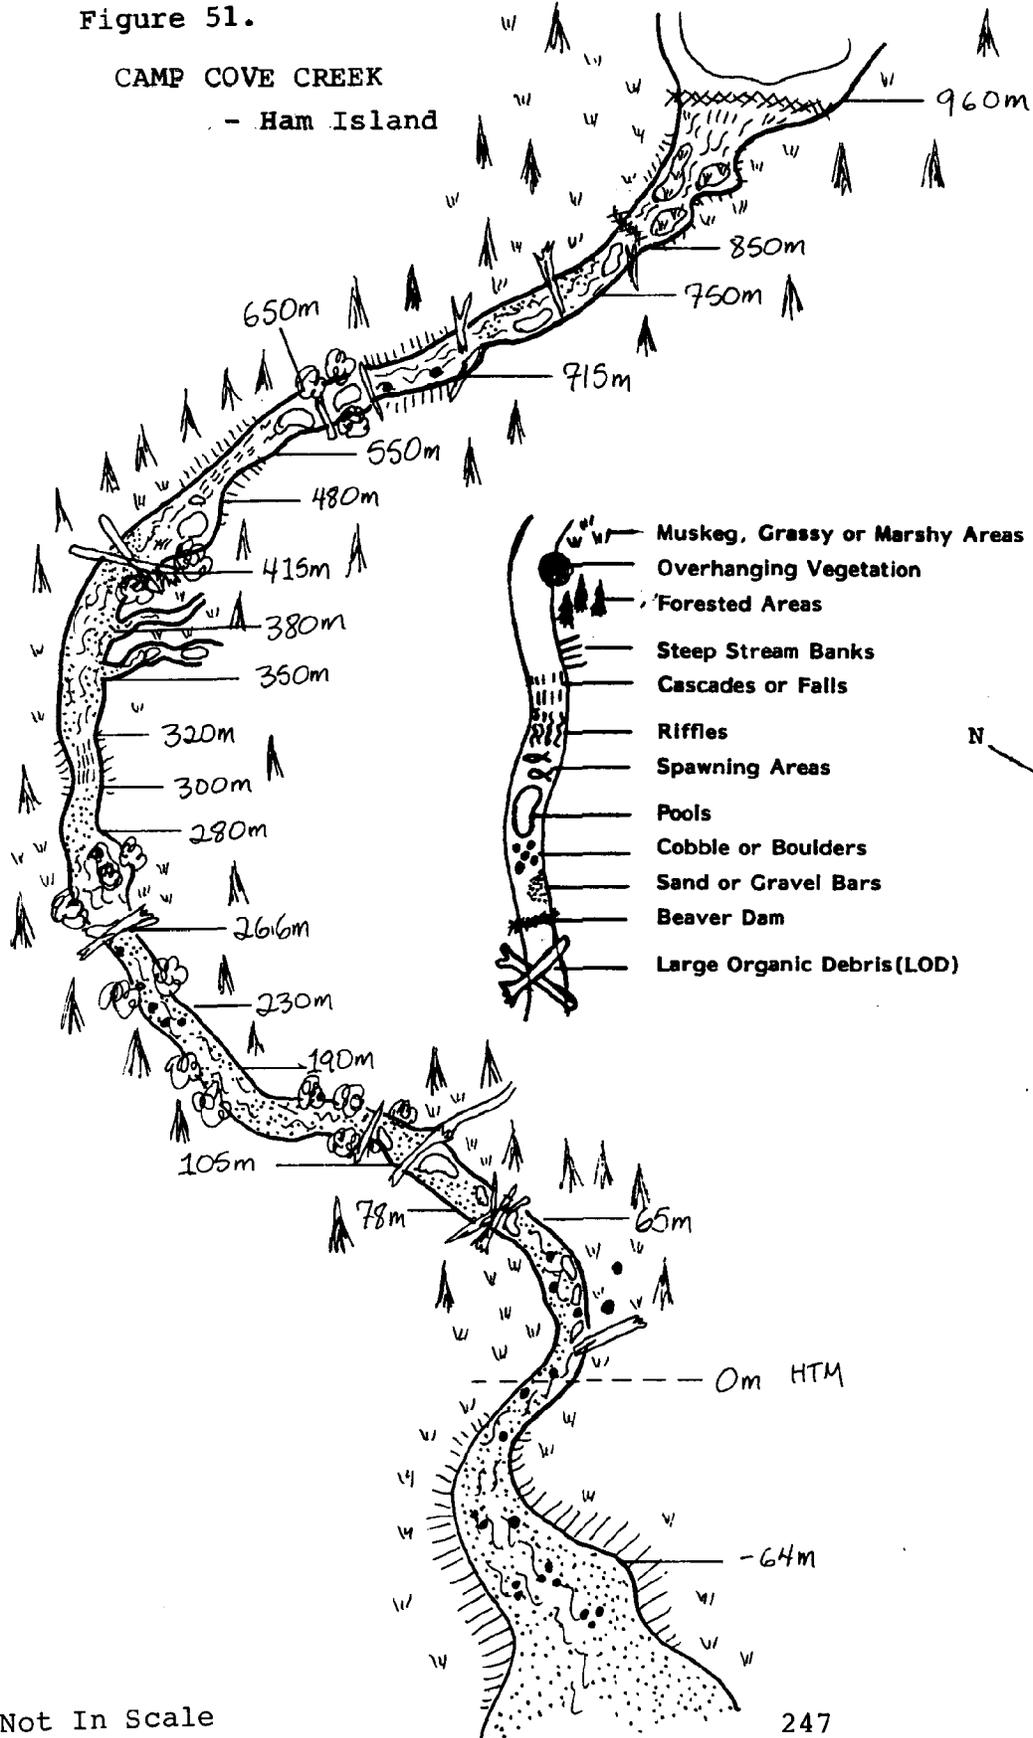

Based on available spawning area, and rearing area recommended escapements are 390 pink, 25 chum, and 5 coho spawning pairs.

Potential Production Summary

Based on the above escapements, and assuming an overall 10% egg-fry survival rate (fair gravels), production potential is 1160 pinks, 124 chum and 28 coho returning to Annette Island.

Figure 51.

CAMP COVE CREEK
- Ham Island

Not In Scale

CAMP COVE CREEK (HAM ISLAND)

Watershed No. 300-01
Stat. No. 101-24-098

-64m Average Stream Width (ASW) = 2.5m, 30% gravels (.50m² available spawning area).

0m High Tide Mark (HTM).

65m Canopy closes in to 90% shading; ASW = 2.5m, bottom is 40% boulders and cobble, 10% gravels (16m² spawning area).

78m LOD pile.

105m ASW = 2.5m, ASD = .2m, a large pool here provides excellent rearing habitat next to a gravel bar (5m² spawning area); a tributary with .25 cfs flow enters here and also provides some excellent rearing habitat.

190-230m ASW = 2.0m, 80% spawning gravels (64m² area).

230-266m ASW = 2.0m, 20% spawning gravels - large size (14m² area). At 266m is an old root tangle, LOD and mainly fine sediment on the bottom.

280-300m ASW = 1m, 90% spawning gravels (18m² area).

300-320m Creek flows over a bedrock channel.

320-415m ASW = 3m, ASD = .2-.3m, gradient lowers and gravels begin again - 10% spawning gravels in bottom (29m² area available). At 380m is a tributary (less than .25 cfs flow) with some rearing area and evidence of redds. At 380m is another .25 cfs flow tributary. At 415m is a root tangle, a possible barrier at low flow and a pool above.

480-550m Creek flowing across bedrock, at 550m and above, gravels are sparse.

650m Root tangles and LOD form good sized pools.

715m² ASW = 2m, a deep, slow flowing channel here with too many fine sediments mixed with cobble for spawning.

715-780m Some gravel bars occur, ASW = 1.5m, with about 40m² total spawning area.

850-960m Old beaver dam at 850m, and creek above is channellized and the bottom is all fines. At 960m, is a beaver dam with a huge pond (creek origin). End of spawning habitat here and survey.

Spawning Area:

Intertidal 50m² area
Above HTM 186m² area

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
-----------------------------------	-----------------------	----------------------

Limited, some undercuts and LOD below barriers, above barrier

Available Cover

Sparse - caddisflies, mayflies and diptera.

Aquatic Invertebrates/Available Food Source

Sparse - some algae.

Aquatic Vegetation

Blueberry, alder, skunk cabbage, devil's club, under a spruce and hemlock canopy.

Terrestrial Vegetation

25% to first barrier - due to canopy and topography. 75% above barrier due to riparian vegetation, canopy

Shading and topography.

Limited - very little below the first barrier. Moderately abundant above the barrier in beaver ponds and

Extent and Quality of Rearing Area

under LOD - could rear coho above barriers.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink and chum utilize this creek.

Use by Fish

Subsistence fishing rare.

Use by Fishermen

Wildlife Present

Beaver activity and wolves observed.

Comments and Recommendations

This creek is a major producer of pink and chum salmon due to the extensive high quality spawning areas; however, low creek velocity could reduce the potential production expected with the area present. There is potential coho rearing and spawning area above the falls, but the production increase may not justify the cost of a fish passage (need benefit:cost analysis and a more detailed stream survey above the barriers).

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
5/5/72	None Seen				
1974	Pinks	Adult	100	--	USFWS Estimated Total Escapement
1975	Pinks	Adult	1768	--	USFWS Estimated Total Escapement
1976	Pinks	Adult	2094	--	USFWS Estimated Total Escapement
9/7/80	Pinks mainly (mixed)	- Adult	1000	--	Fish counted outside mouth - aerial count.

Survey(s) and Dates Conducted

C. Huntington, 6/20/81, E. Biggs, 8/12/80, and USFWS, 5/5/72

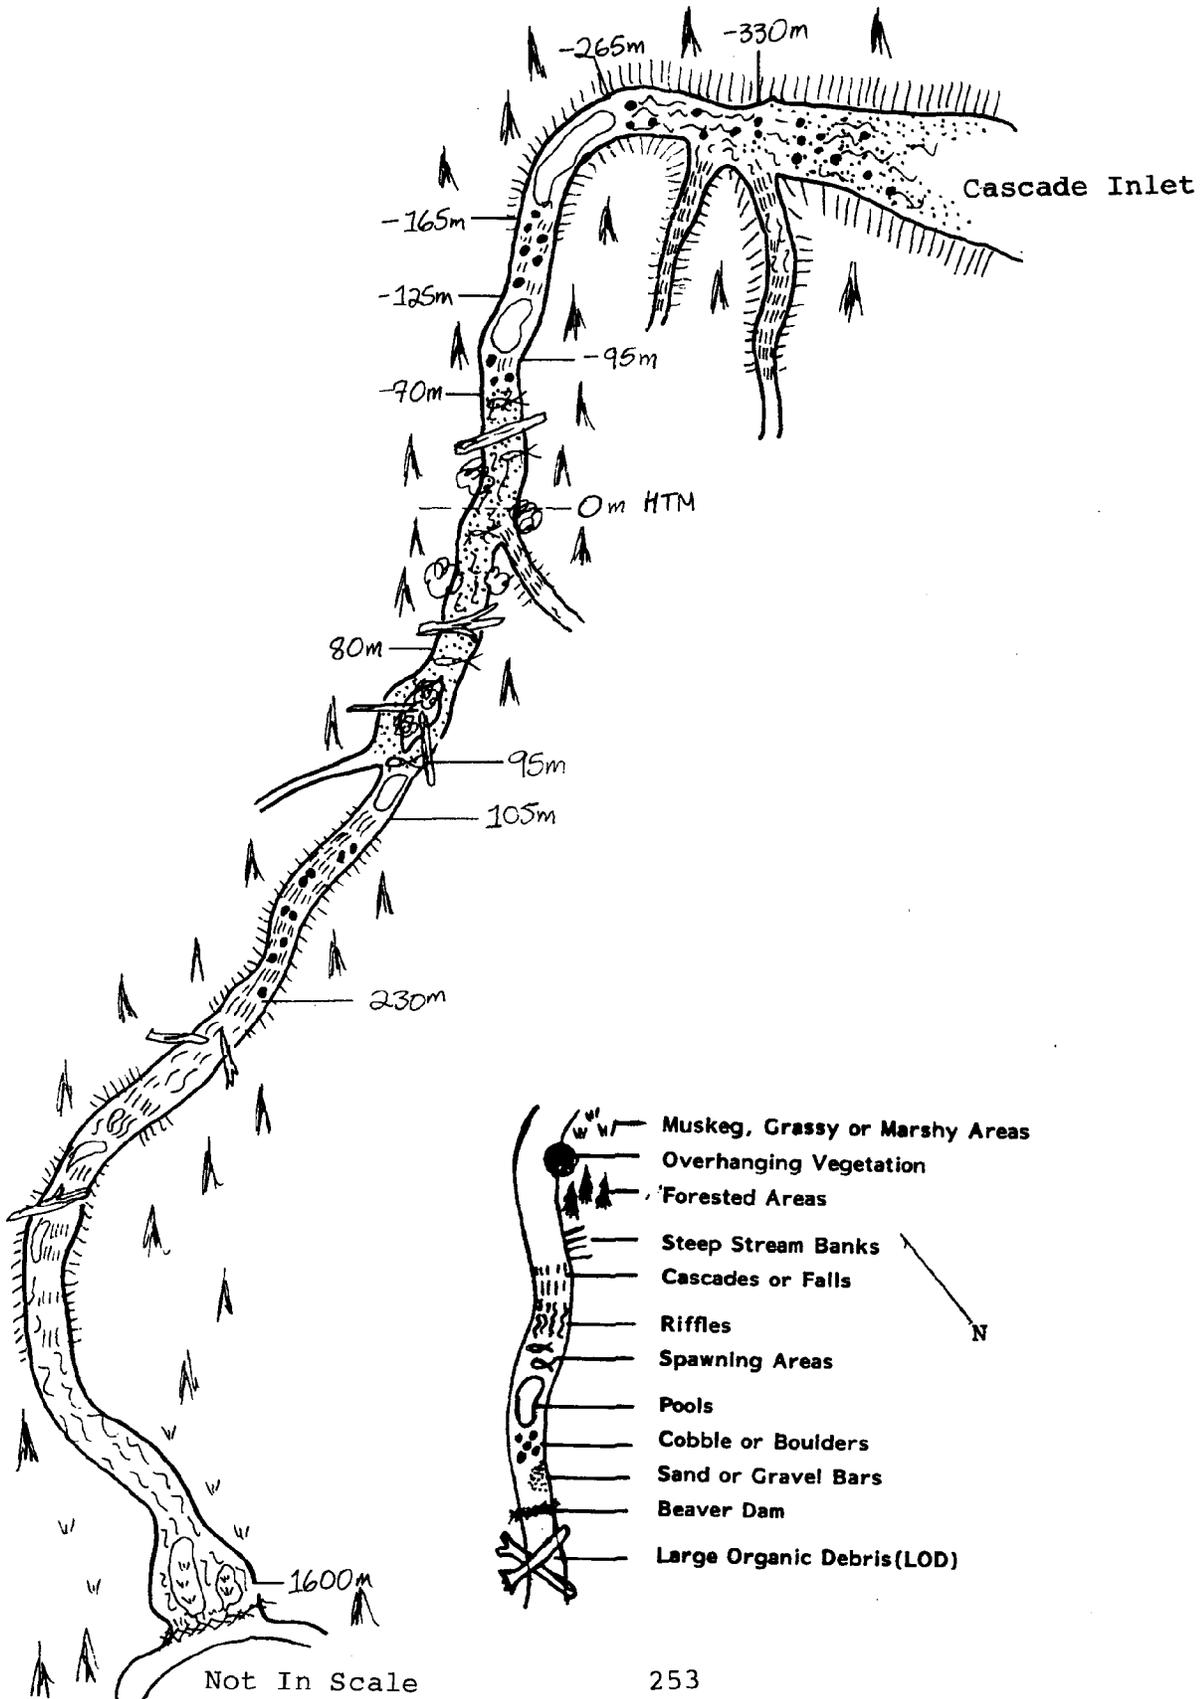

Recommended Escapement

Recommended escapements based on the available fair-good quality spawning areas (not including any of the marginal areas that fish could spawn in, but survival would be limited) are 2100 pink, 137 chum and 5 coho spawning pairs.

Potential Production Summary

Based on the above escapements and an assumed egg-fry survival rate of 10%, a production potential estimate is 6240 pinks, 680 chum, and 30 coho returning to Annette Island. Potential coho rearing and spawning remains above the barrier falls remains unsurveyed at this time.

Figure 52. CASCADE CREEK I

CASCADE CREEK I

Watershed No. 301-02
Stat. No. 101-42-057

- 330m Six cfs flow tributary enters, with possible bedrock cascade barrier at mouth - at 45m up is a 2.5m high stepped falls and possible barrier, no spawning or rearing in tributary. In main channel here and below are steep stream banks. Just above -330m is a .3 cfs flow tributary with a possible cascade barrier at the mouth - no spawning or rearing area is available.
- 265m No good spawning gravels below this point.
- 265 to -165m Average Stream Width (ASW) = 1.5m, Average Stream Depth (ASD) = 2m, looks like one large pool over 1m deep average, gravels are fine.
- 165 to -125m Boulder run (no gravels).
- 125 to -95m Pool 12m wide and average 1m deep, maximum depth is 2m - some fine gravels in the bottom.
- 95 to -70m Boulder run.
- 70-0m ASW = 16m, ASD = .5m, average velocity is .5 fps; best spawning area so far (560m² available spawning area). At 0m is High Tide Mark (HTM). Just above 0m is a 1.5 cfs flow tributary with a 2.5m barrier falls at the mouth.
- 0-80m ASW = 16m, ASD = .5m, average velocity is .5 fps, "Fair" gravels in glide (some fines mixed in - 640m² spawning area available).
- 80-95m Channel braids around island; good quality spawning gravel in northern side channel (50m² area), some spawning gravels occur just above braiding (10m² area). At 95m, a .1 cfs flow tributary enters with no available spawning or rearing area.
- 105m Stepped cascade and falls (probable barrier) with a plunge pool.
- 105-230m Bedrock, boulder channel; 5m stepped falls (probable second barrier) at 230m.
- 230-1600m Gradient decreases gradually; bottom is mainly bedrock and boulders. At 1600m, is a beaver dam and a large pond (small lake). End of survey.
- Spawning Area: Intertidal 560m² Fair to good quality spawning gravels.
350m² marginal quality gravels.
Above HTM 700m² of fair to good quality spawning gravels to the barrier cascade.

Spawning Area

30% gravels, 10% cobble, 5% bedrock, 10% small boulders, 45% fines (sand and silt).
Overall Stream Bottom Composition Angular gravel and some fines present; marginal quality gravels.

Gravel Compaction

Gravels become less abundant (increasing fines) above 850m and stream splits after that. 714.5m² area
Spawning Area Available Above High Tide Mark (HTM) available.

340m² of marginal quality gravels - survival of eggs is questionable due to low gravel quality, stream
Intertidal Spawning Area flashiness and channel instability.

Rearing Area

Numerous pools. -- -- Some up to 15m long.

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
LOD abundant, undercut banks, and root wads provide a fair amount of cover.		

Available Cover
Sparse

Aquatic Invertebrates/Available Food Source
Sparse - some marine algae in lower end.

Aquatic Vegetation
Vanilla leaf, skunk cabbage, ferns, mosses, alder with some stunted hemlock (predominately) canopy.

Terrestrial Vegetation
Intense in upper creek - 85% due mainly to bank vegetation.

Shading
There is abundant coho rearing habitat in upper half of the creek, however, the low flow in summer may limit

Extent and Quality of Rearing Area
numbers produced.

Reported and Suspected Use of Stream by Fish and Fishermen

Pink, chum, and coho utilize creek.
Use by Fish

No known fishing.
Use by Fishermen

Wildlife Present

--

Comments and Recommendations

This is the major creek producing salmon of the Hassler Harbor Creeks; however, it produces low numbers.
 The possible intermittent flow may reduce survival of eggs, alevin and fry and it is surprising no spawners have been seen. The creek does have some good coho habitat.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/18/72	None seen - spawners were expected!				
6/18/81	Coho	Fry	Over 100		In abundance above 400m.

Survey(s) and Dates Conducted

J. Yuska, 6/18/81 and USFWS, 9/18/72

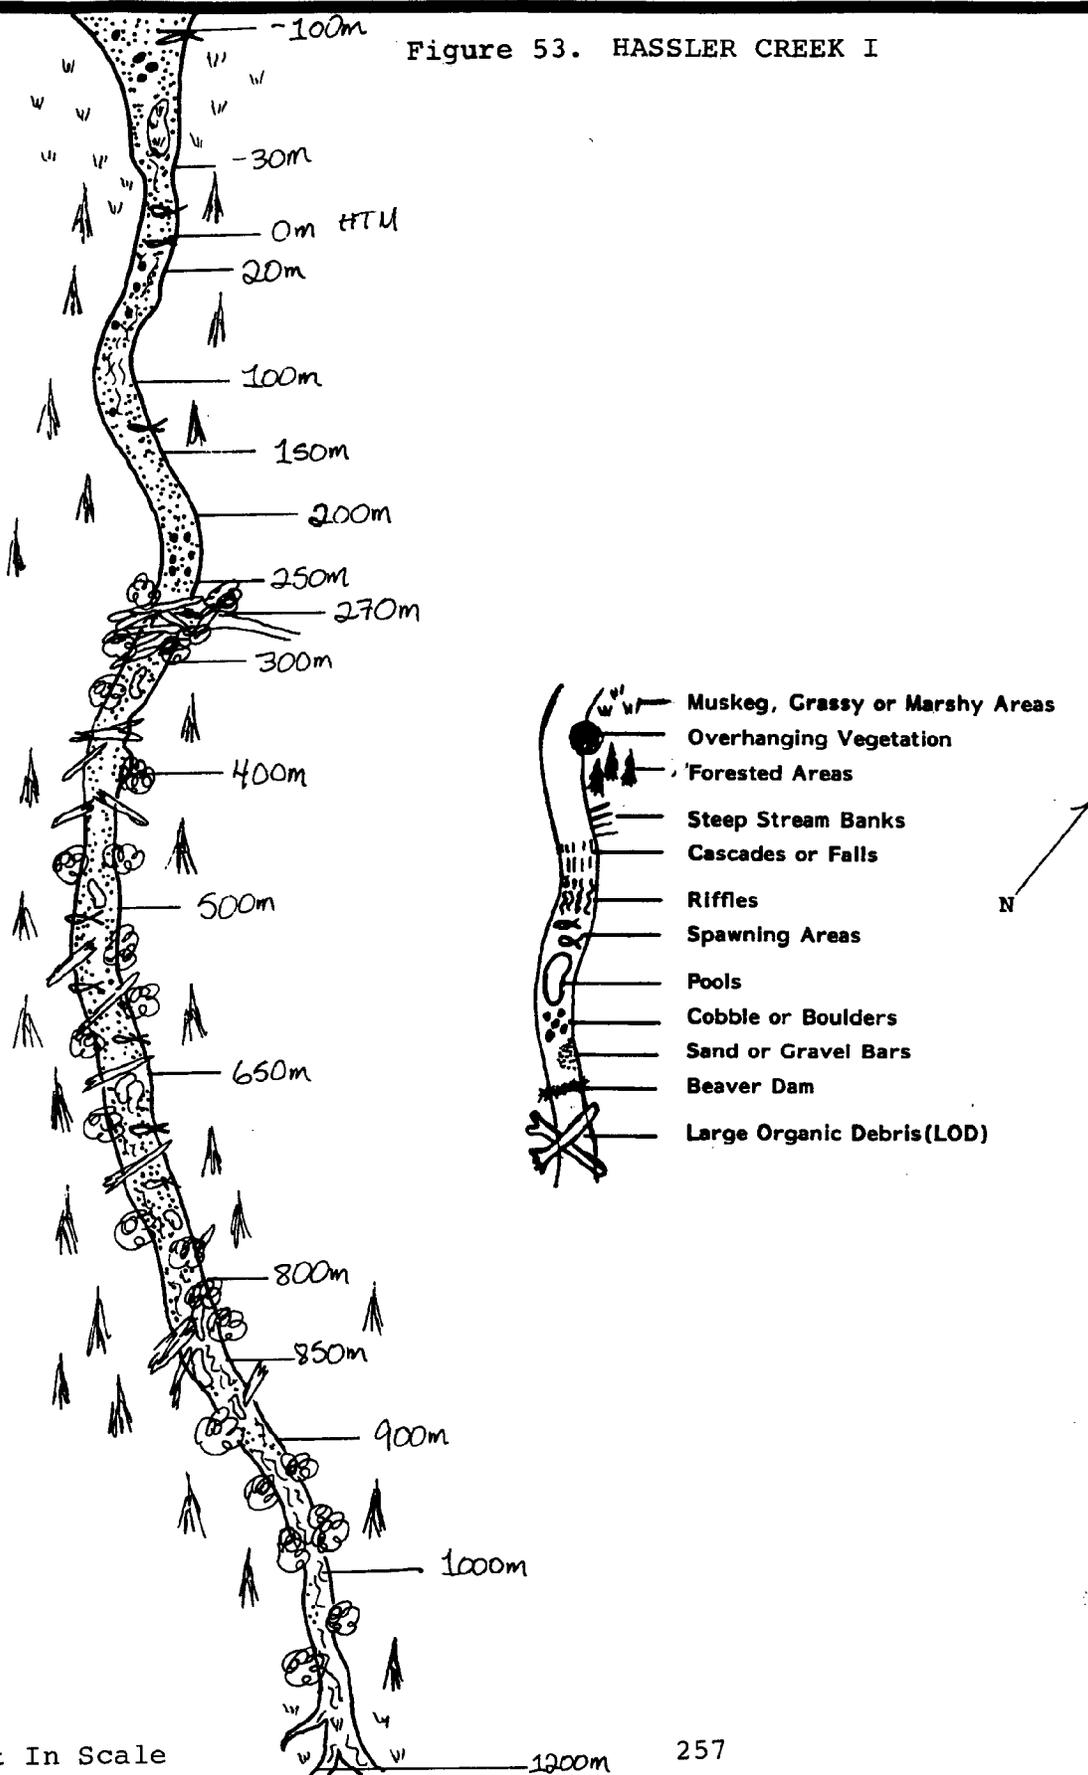

Recommended Escapement

The intertidal spawning area was not included in the estimate of recommended spawners because of the marginal gravel quality and abundance of habitat above it (although pinks could utilize it). Therefore, recommended escapements are 1200 pink, 80 chum, and 5 coho spawning pairs.

Potential Production Summary

A 1.2% egg-fry survival rate will be assumed due to the poor gravel quality. Production potential is estimated at 430 pinks 50 chum and 4 coho returning to Annette Island originating from this creek.

Figure 53. HASSLER CREEK I

Not In Scale

HASSLER HARBOR CREEK I

Watershed No. 202-01
Stat. No. 101-42-058

-100 to -30m Average Stream Width (ASW) = 6m; bottom composition:
60% spawning gravels, 30% pebbles and fines, 10%
boulders.

-30 to 0m ASW = 6m, 50% gravels. At 0m is High Tide Mark
(HTM).

0-20m 70m² spawning area available.

20-100m ASW = 4m; bottom composition: 5% gravels, 40% cobble,
60% small boulder (16m² spawning area).

100-150m ASW = 6m, 50% gravels (150m² spawning area).

150-200m ASW = 6.5m, 20% gravels (65m² spawning area).

200-250m ASW = 2.5m; steep banks (45°); bottom composition:
75% boulder, 20% bedrock, less than 5% gravels.
At 250m, bottom is 30% gravels, 25% fines, 20% boulders,
and 20% cobble (15m² spawning area).

270m Tributary comes in under 10 logs across the main
channel (less than 5% gravels).

300-400m Excellent rearing habitat with LOD and undercuts;
LOD may be a barrier to adults at low flow. ASW = 3m,
Average Stream Depth (ASD) = .15m.

400-650m ASW = 3m, 20% gravels (150m² spawning area). Low
gradient with excellent rearing areas (undercut banks).

650-800m ASW = 3m, bottom has 50% gravels (225m² spawning area).

800-850m ASW = 2m, 20% gravels (20m² spawning area).

850-900m Less than 5% gravels, but excellent rearing habitat,
many coho fry observed.

900-1000m ASW = .7m; less than 5% gravels. Moderate gradient,
and fry are still numerous.

1000-1200m ASW = .5m, moderate gradient with less than 5% gravels,
no more coho fry seen. End of survey at 1200m where
creek splits up into the muskeg.

Spawning Area:

Intertidal 342m² area available
Above HTM 715m² approximate area available

Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall

Spawning Area

Below falls: 55% gravel, 15% pebble, 15% sand, 7% silt, 2% cobble, 2% rubble, 2% boulder, 2% bedrock.
 Overall Stream Bottom Composition

Extensive - many fines in gravel.
 Gravel Compaction

Limited - 30m² below falls and only about 4m² potential area above falls. Survival of eggs is probably
 Spawning Area Available Above High Tide Mark (HTM)

low due to fines in gravel and low velocity.

200m² of marginal quality area is available; poor due to low velocity and fines in gravel.

Intertidal Spawning Area

Rearing Area Pools are mainly caused by beaver activity and falls. p:r = 5:1 at low flow. Pool under falls is .35m/ 15 x 10m / -- One pool (below falls) is

Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range

Fair amount due to beaver ponds, overhanging vegetation and pools.

Available Cover

Sparse - diptera and trichoptera observed.

Aquatic Invertebrates/Available Food Source

Cedar-like moss is abundant as well as filamentous algae.

Aquatic Vegetation

Skunk cabbage - grasses and sedges under a canopy of spruce, hemlock and cedar.

Terrestrial Vegetation

50% above falls, 30% below.

Shading

Fair coho habitat exists above the cascade; however it is limited due to small size of creek.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks, chums and coho may use this creek.

Use by Fish

No fishing know.

Use by Fishermen

Wildlife Present

Heavy beaver activity and influence on stream.

Comments and Recommendations

This creek produces low numbers of any salmonid, however, it is utilized. Because of low velocities, flows and compacted gravel, survival of eggs and alevins is probably low.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/25/72	None seen - pinks were expected.				
6/18/81	Coho	Fry (50mm)	2		In tributary

Survey(s) and Dates Conducted

C. Huntington, 6/18/81 and USFWS, 9/25/72

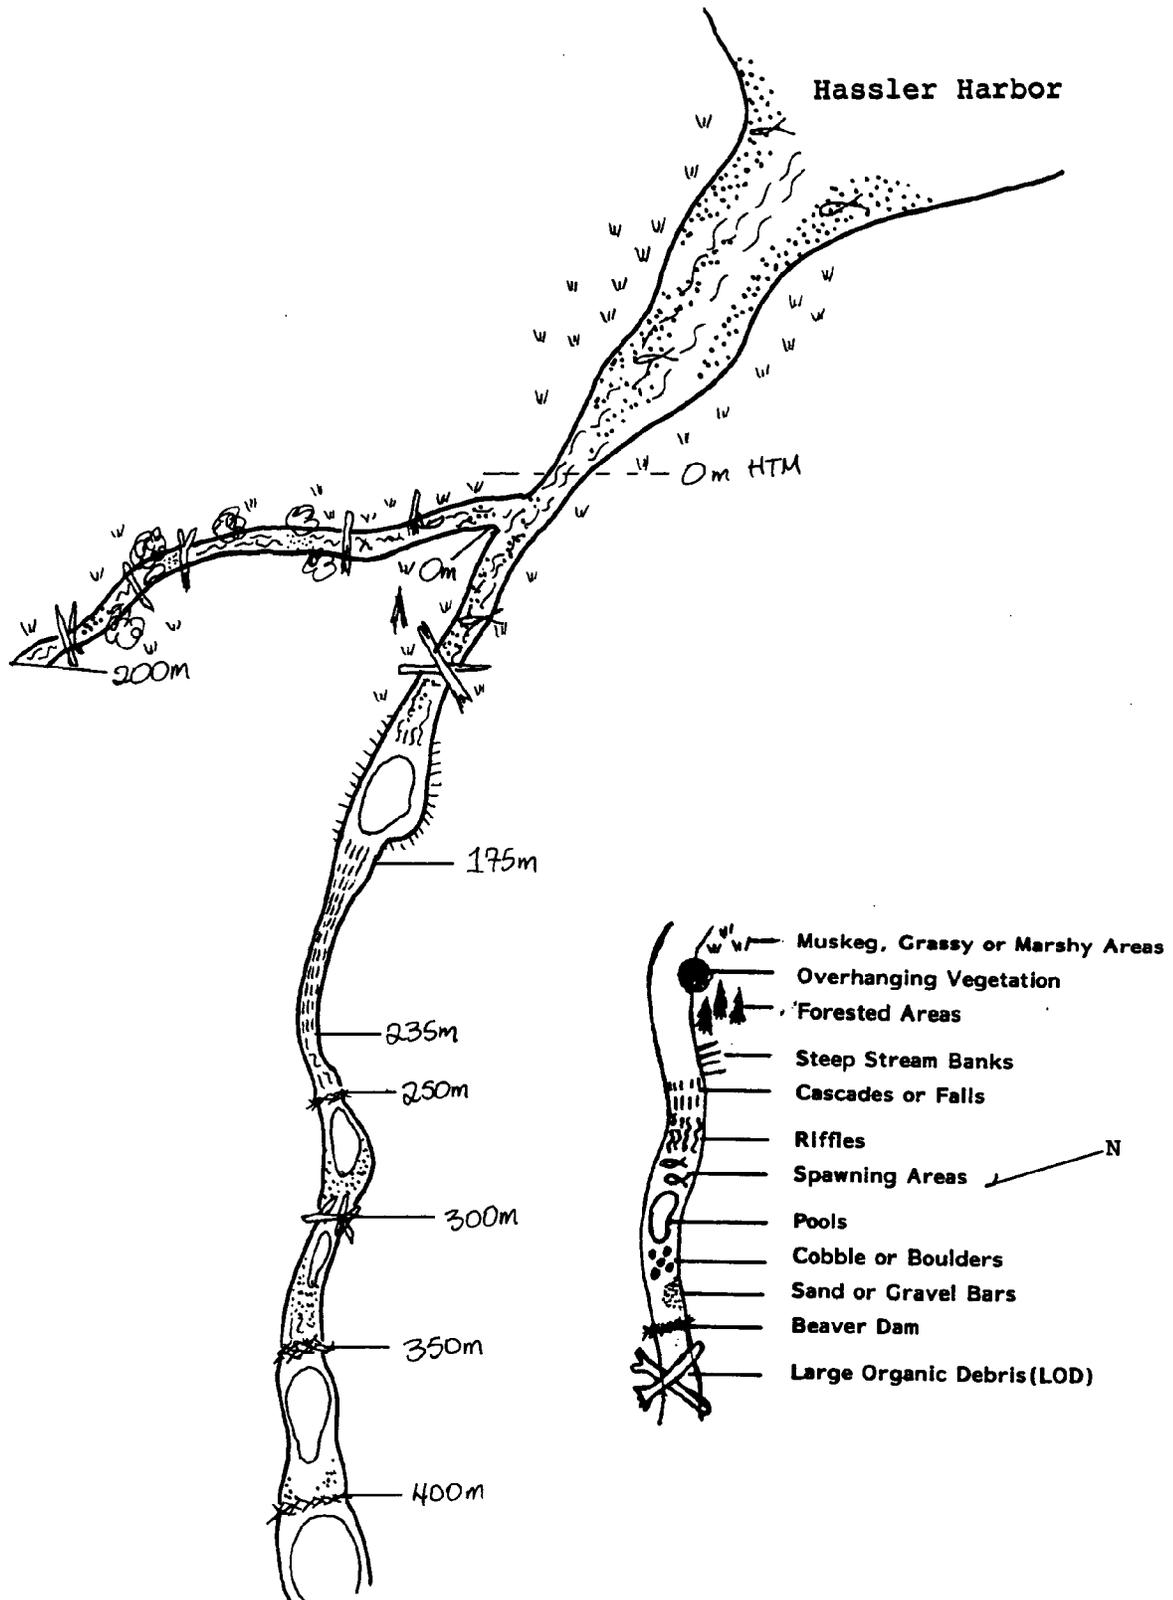

Recommended Escapement

Based on current available spawning area, 380 pink and 25 chum spawning pairs could utilize this creek. Coho could not because of the limited rearing area available.

Potential Production Summary

Based on the above escapements and a 1.2% egg-fry survival rate (marginal gravels), potential production is estimated at 135 pinks and 15 chum returning to Annette Island.

Figure 54. HASSLER HARBOR CREEK IV

Not In Scale

HASSLER HARBOR CREEK IV

Watershed No. 202-03
Stat. No. 101-42-060

- Intertidal 200m² available spawning area.
- 0m High Tide Mark (HTM). Tributary enters just above 0m with less than .1 fps velocity, but approximately 5m² spawning area available; good rearing habitat here with pools to .7m deep, root tangles, undercut banks, and LOD, also abandoned beaver dams and 40% shading - tributary surveyed to 200m.
- 0-175m 30m² available spawning area, although gravels have alot of fines mixed in; just below 175m is a large pool 15 x 10m, .35m deep. At 175m is a small, bedrock falls that may be a barrier to pink salmon; above falls is 4m² of marginal quality spawning gravels.
- 175-235m Bedrock channel.
- 250m Beaver dam, with pond behind it.
- 300m Old beaver dam, with small pond.
- 350m Beaver dam 1m high, a probable barrier because of a root tangle at the base.
- 400m Additional dam, end of survey (no more spawning habitat).

Spawning Area:

- Intertidal 200m² of marginal to fair quality spawning area
Above HTM 39m² of marginal quality spawning area.

1 x 2m/ up to 12 x 40m

Pool/Riffle Frequency (P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Abundant: some braiding occurs, with some bank undercutting; LOD and organic matter behind beaver dam.
Available Cover

Abundant and diverse / mayflies, caddisflies, ephemeroptera and stoneflies observed.
Aquatic Invertebrates/Available Food Source

Some microalgae and some mosses; alot of green filamentous algae in riffles
Aquatic Vegetation

Stunted trees in muskeg below meadow - grasses and herbs in meadow.

Terrestrial Vegetation

30% due to topography and canopy below meadow. 10% in meadow due to steep banks.

Shading

Extensive above and near beaver dam.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Currently, only cutthroat utilize this stream and lake.

Use by Fish

No fishing.

Use by Fishermen

Wildlife Present

Active beaver dam and lodge in alpine meadow. Deer seen in meadow.

Comments and Recommendations

A fish ladder over the falls could turn this system into a major coho producer as well as open area to pink and chum. A more thorough stream survey to lake is recommended along with a benefit:cost study prior to enhancement. However, stocking this lake with excess fry for rearing could prove fruitful.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/20/73	Cutthroat	Adult	1	--	In Triangle Lake
9/21/79	Cutthroat	Adult (13-15 cm.)	1	--	In Upper Triangle Creek
6/7/81	None Seen				

Additional Water Quality Data:

7/18/79 - Above Falls: Flow - * Temp (Water) - 21.3C; D.O. 10.3ppm (10.4ppm riffle)
7/19/79 - Above Falls: Flow - 6.47 cfs;
 Below Falls: Flow -25.47 cfs?; Temp (Water) - 18.5C; D.O. 10.4ppm, Conductivity-140 ohms/cm²
8/21/79 - Above Falls: Flow - 7.20 cfs?; Temp (Water) - 18.0C; D.O. 10.7ppm
 Below Falls: Flow - 2.76 cfs?; Temp (Water) - 16.5C; D.O. 7.5ppm
9/21/79 - Above Falls: Flow -39.85 cfs?; Temp (Water) - 13.0C; D.O. 10.2ppm; Conductivity-175 ohms/cm²
 Below Falls: Flow -35.11 cfs?; Temp (Water) - 12.0C; D.O. 10.8ppm; Conductivity-170 ohms/cm²

*Flow measurements are questionable.

Survey(s) and Dates Conducted

E. Biggs, 6/18/81 and USFWS, 9/20/73 and Pacific Rim Planner, Inc., 7-9/79

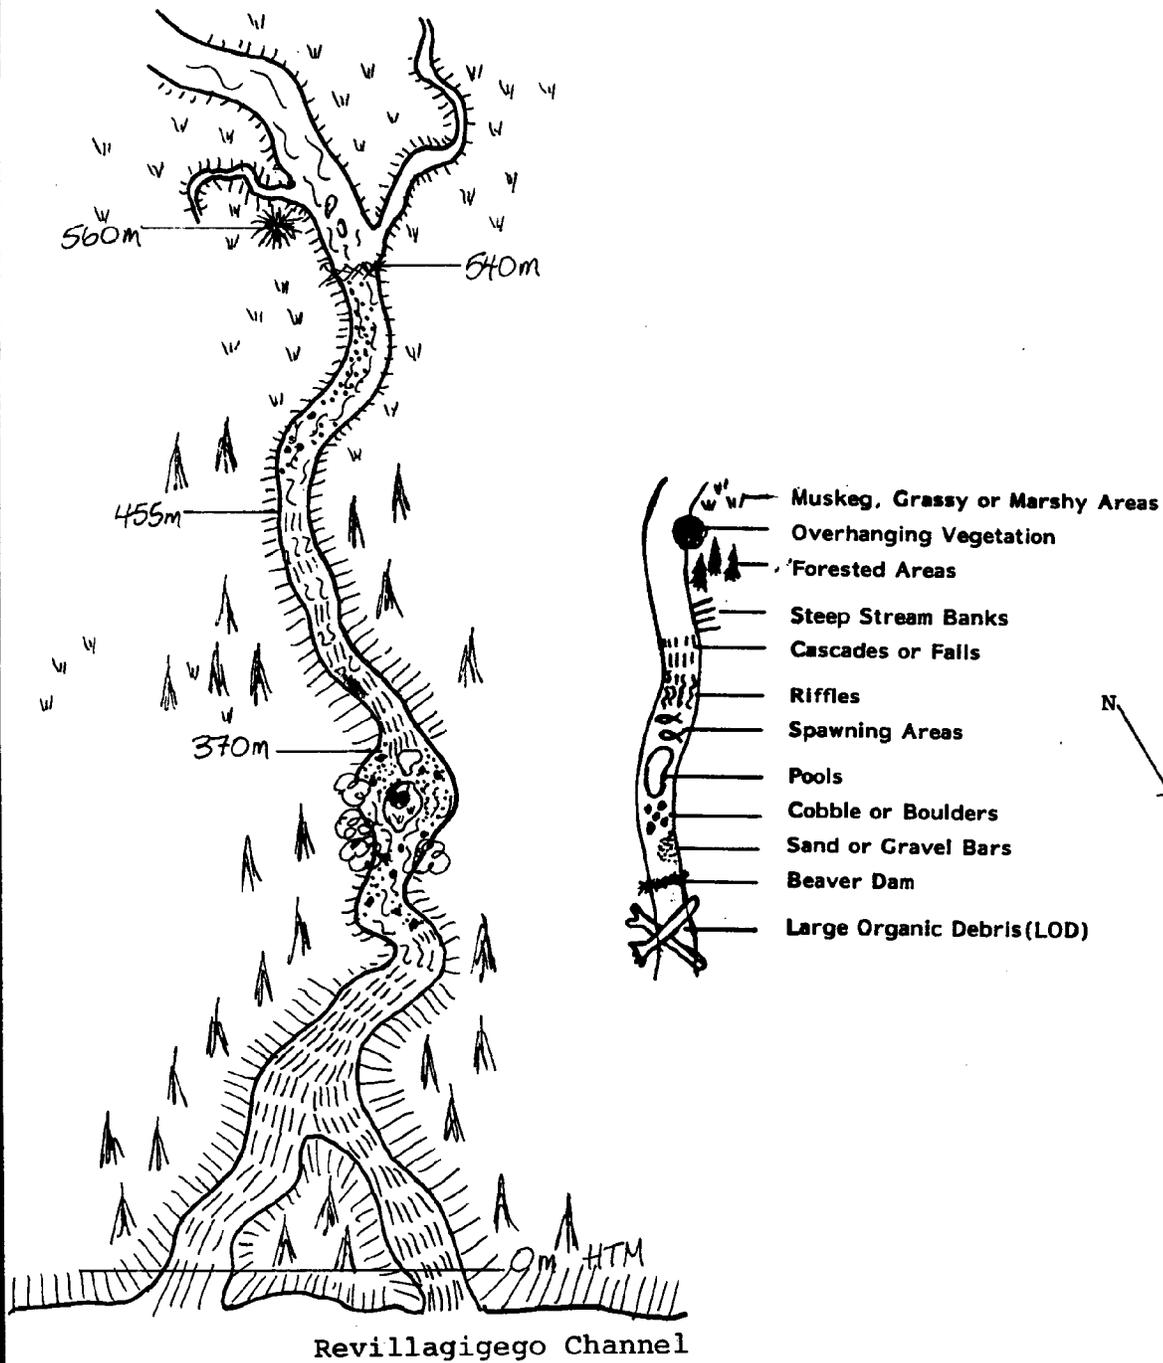

Recommended Escapement

None currently.

Potential Production Summary

Much unsurveyed spawning area probably exists above the falls, and since there is alot of potential rearing area, a closer scrutiny of this system may prove productive.

Figure 55. TRIANGLE CREEK

Not In Scale

TRIANGLE LAKE CREEK

Watershed No. 202-04

Stat. No. 101-42-061

- 0m High Tide Mark (HTM), creek flows over impassable intertidal barrier falls. Limited spawning area above falls, probably unusable at high flows.
- 370m Second set of cascade falls (may be a velocity barrier). Creek begins flowing through a muskeg meadow with a wooded margin next to the channel.
- 370-455m Cascade, bedrock riffle.
- 455-540m Gradient lowers; at 540m is a beaver dam at the margin of an upland meadow, through which the creek meanders; below dam are some gravels, but they are mixed with fines; good habitat probably exists above the upland meadow toward Triangle Lake. Beaver lodge occurs just above dam at 540m. End of survey.
- Spawning Area: Limited. Currently none available due to barrier falls.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

--

Comments and Recommendations

USFWS recommends leaving creek in present stated. Additional surveys are needed to map spawning areas and determining production potential for benefit:cost analysis to enhancing creek system (putting in fish passage in above Nadzaheen).

Survey(s) and Dates Conducted USFWS, 9/25/75

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Todd Stream		101-42-065		201-02	
Stream		Number		Geocode	
Flows from Upper to Lower Todd Lake		Upper Todd Lake		Apline Lake (15.6 acres in area)	
Location		Origin		Watershed Type	
6/21/81	Entire section - .25 mi.	None		Low	+1 ft
Date Surveyed	Section Surveyed	Barriers		Stage	Flood Height
2%	12 cfs / 13 cfs (8/2/73)	Under 1 fps/ 1fps (8/2/73)		4.5m / --	.3m / --
Ave. Gradient	Flow / Range	Ave. Velocity/Range		Ave. Width/Range	Ave. Depth/Range
Soils with grasses - some channelization and bank erosion		occurs, but relatively stable.		Three muskeg drainages enter stream.	
Streambank Composition		/ Stability		Tributaries	
Water Quality 8/2/73:					
	19.5C	18.9C	7.0	--	--
	--	17.5C	14.0C	--	--
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color
					Brown
					D.O.
					CO2
Trace (8/2/73)					
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall		

Spawning Area

80% usable spawning gravels - mixed with some mud.
Overall Stream Bottom Composition:

Some mud in gravels.

Gravel Compaction

Approximately 1990;² of marginal to poor quality gravels - but usable - survival of eggs may be

Spawning Area Available Above High Tide Mark (HTM)

low if velocity is low and because of fines.

Not applicable.

Intertidal Spawning Area

Rearing Area

Some pools - pools in 40% of creek and riffles in 30%.

Pool/Riffle Frequency (P:R Ratio)

Ave. Pool Depth/Range

Ave. Pool Size/Range

Some available; root wads and undercut banks - provide it.

Available Cover

Some present - mayflies observed.

Aquatic Invertebrates/Available Food Source

Not abundant, but some mosses and filamentous algae occur.

Aquatic Vegetation

Few trees - mainly sedges, grasses, and some bog orchids, columbine, bunchberry, dogwood and thimbleberry.

Terrestrial Vegetation

10% due to banks and vegetation.

Shading

Some off channel areas and root wads, with a slow velocity provide rearing habitat.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Currently only cutthroat and Dolly Varden utilize stream.

Use by Fish

No known historic use.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

Moderately abundant spawning and rearing areas are available for trout or landlocked salmon. It could support sea-run salmon if a fish passage were constructed. Lake system deserves a benefit:cost study and production potentials should be examined. The lake looks productive and may provide alot of rearing area.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
Spring, 1973	Rainbow	Fry	4850	--	Stocked in Upper Lake - none seen in 1981.
8/2/73	Dolly Varden	49-178mm fork length	24	--	Caught in gillnet USFWS claims to have caught a coho smolt, however, this is questionable as barrier prevents salmon migration into Todd Lake.
6/21/81	Cutthroat	Fry	10	--	No salmon fry observed.

Survey(s) and Dates Conducted

J. Yuska, 6/21/81 and USFWS, 8/2/73

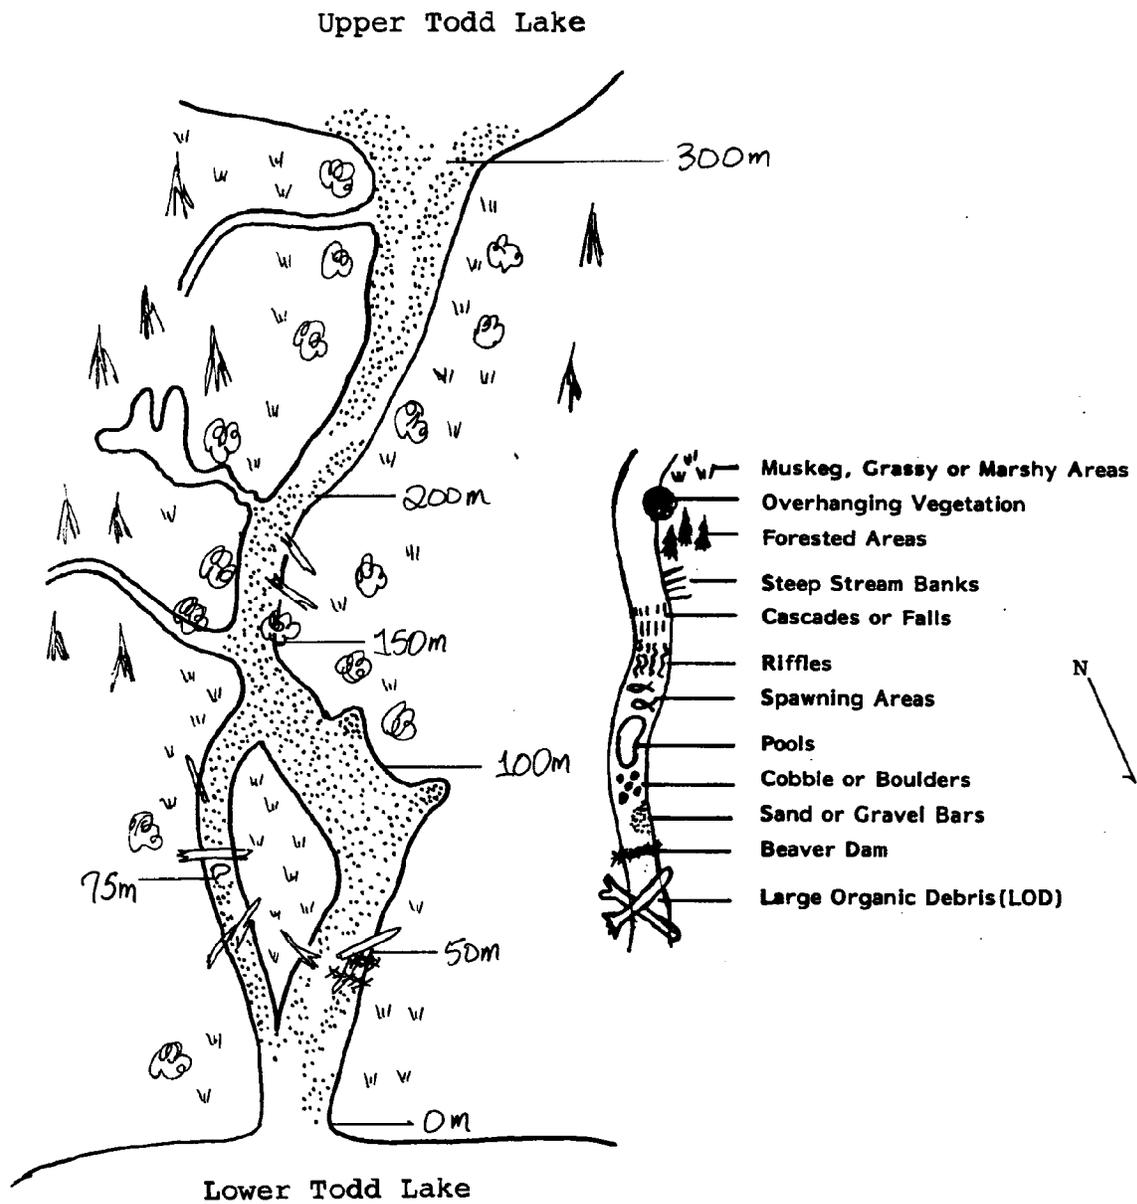

Recommended Escapement

None made due to barrier falls in Nadzaheen Creek.

Potential Production Summary

Because of the fine gravels, sockeye and coho would probably not utilize this stream and because of its distance from the estuary, pink and chum could not successfully utilize it.

Figure 57. TODD STREAM

Not In Scale

TODD STREAM

Watershed No. 201-02
Stat. No. 101-42-065

- 0m Lower Todd Lake. Just above 0m, a 75m long side channel flows off to the east side of the main channel with a bottom composed mainly of gravel and mud.
- 0-100m Average Stream Width (ASW) = 8m, Average Stream Depth (ASD) = .5m, 80% spawning gravels; low velocity flow. At 50m, beaver dam was started.
- 100-200m ASW = 6m, ASD = .25m, 100% usable spawning gravels - large channel with a few root wads. At 150m is a 75m long tributary with .125 cfs flow - no gravels. At 200m is a 50m tributary draining muskeg - no spawning area.
- 200-300m ASW = 10m, ASD = .15m, 75% spawning gravels. At 300m is Upper Todd Lake with a muskeg drainage tributary entering just below.

Spawning Area:

All Freshwater - 1990m² area available, at present, to cutthroat and rainbow trout only.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Lower Todd Lake Creek	101-42-066	201-06
Stream	Number	Geocode
Flows NE into Lower Todd Lake, 2 mi long./ slope run-off, some muskeg run-off./ slopes and a few muskeg		
Location	Origin	Watershed Type
6/21/81	610m from mouth to barrier.	Cascades at 610m
Date Surveyed	Section Surveyed	Barriers
1-2%	10 cfs/4.6 cfs (9/27/75)	1 fps / --
Ave. Gradient	Flow / Range	Ave. Velocity/Range
Steep banks of fragmented rock colonized by vegetation/ Stable, little LOD influence.		
Streambank Composition	Stability	Tributaries
		Two small tributaries enter creek.

Water Quality								
240m above mouth	17.5C	12.0C	7.5	(9/27/75)	Clear / None	Light Amber	-- --	
Sample Site	Temp.-Air	Temp.-Water	Ph	Clarity/Turbidity	Color	D.O.	CO2	
--	--	--	--	Water looks like mainly mountain run-off, may be				
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				flashy.	

Spawning Area

70% gravels, variable in size, 15% boulders and cobble, 10% bedrock, 5% fines and organic matter.

Overall Stream Bottom Composition

Flat, angular gravels (slate)

Gravel Compaction

Approximately 1960m² of poor to good quality spawning area is available.

Spawning Area Available Above High Tide Mark (HTM)

Not applicable.

Intertidal Spawning Area

Rearing Area

Few pools - mainly riffles and runs.

Pool/Riffle Frequency (P:R Ratio)	--	--	--
Ave. Pool Depth/Range	--	--	--
Ave. Pool Size/Range	--	--	--

Limited - some LOD, undercut banks and a few root wads.

Available Cover

Sparse

Aquatic Invertebrates/Available Food Source

Scarce - except some moss on submerged rocks.

Aquatic Vegetation

Near mouth, sedges, grasses and herbs are common. Above some blueberries, thimbleberries, skunk cabbage

Terrestrial Vegetation

occurs under spruce, hemlock and cedar.

0-50% - mainly due to topography and canopy.

Shading

Near mouth, beaver dam provides good rearing area and in Lake. Creek, has limited rearing area (few

Extent and Quality of Rearing Area

pools, LOD, or undercut banks).

Reported and Suspected Use of Stream by Fish and Fishermen

Cutthroat and Dolly Varden currently utilize creek.

Use by Fish

No known fishing occurs.

Use by Fishermen

Wildlife Present

Beaver dam just inside mouth of creek.

Comments and Recommendations

Some spawning channels and patchy gravel beds occur of poor to good quality gravels. Rearing is available also. It could support sea-run salmon is passage were installed.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
9/27/75	Dolly Varden	Adults	A few	--	
6/21/81	No salmonids - sticklebacks observed. Numerous tadpoles in creek mouth and lake.				

Survey(s) and Dates Conducted

E. Biggs, 6/21/81 and USFWS, 9/27/75

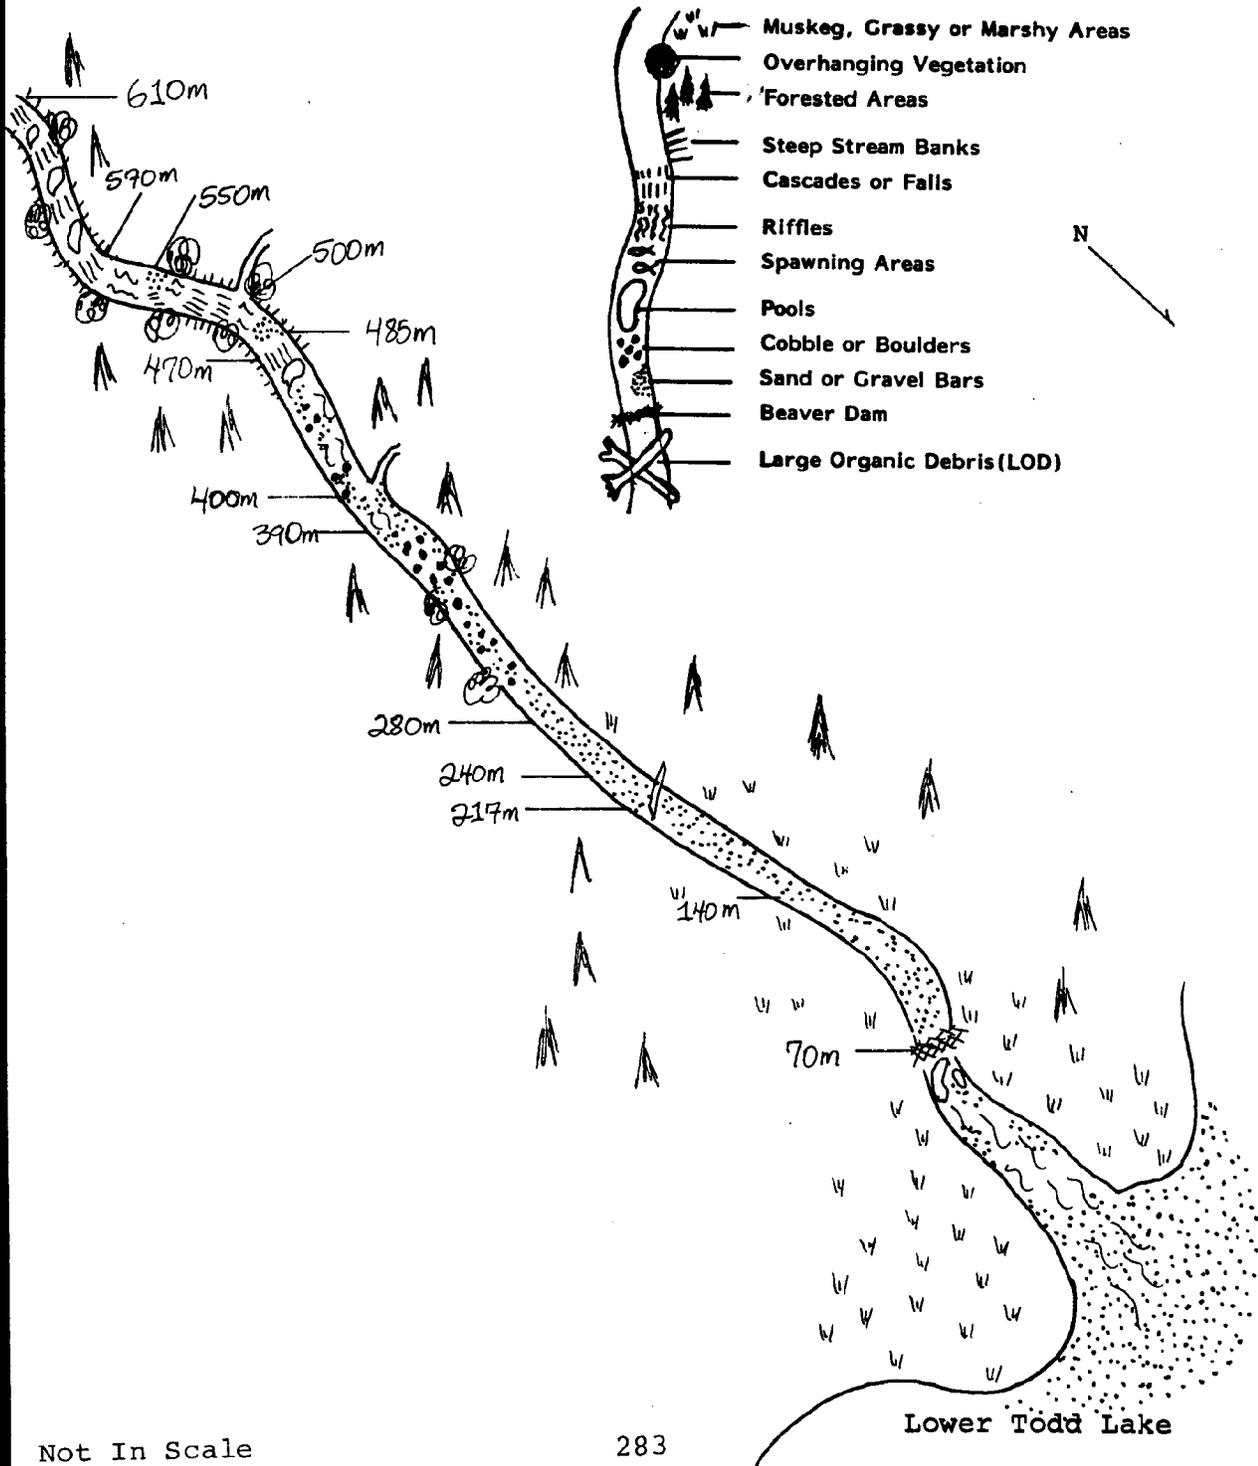

Recommended Escapement

None made.

Potential Production Summary

Because of the extensive spawning area available, 167 coho and 292 sockeye spawning pairs could utilize this creek with a potential production (assuming 10% egg-fry survival) of 942 coho and 1390 sockeye returning to Annette Island.

Figure 58. LOWER TODD CREEK

LOWER TODD CREEK

Watershed No. 201-06
Stat. No. 101-42-066

- 0m Creek mouth with large, shallow gravel bar extending out into Lower Todd Lake.
- 70m Active beaver dam with sediment below that is gravel mixed with mud; 50% usable, but marginal gravels (200m² area).
- 70-240m Slow velocity flow is a wide channel. Average Stream Width (ASW) = 9m, 70% usable with some marginal gravels (1000m² area). At 140m, creek narrows and bottom is hard gravels and mud. At 217m, gravel is cleaner and better quality for spawning.
- 240-280m Velocity increases, ASW = 7m, gravels increase to 90% of bottom (252m² spawning area).
- 280-390m ASW = 5.5m, gravel interspaced with boulders, but is still 75% usable (454m² spawning area).
- 400-470m ASW = 5.5m, rocks become large and flat with gravel interspaced (10% gravels and 44m² spawning area). At 400m, a .25 cfs flow tributary draining muskeg. A pebble bar occurs just above 470m.
- 500m Channel over bedrock; a .5 cfs flow tributary enters in - water is clear, so it is probably mountain run-off.
- 550m 10m² spawning bed, the rest is all bedrock; gradient increases.
- 570m Mineral leaching from rocks here (may be iron oxides).
- 610m Bedrock cascade, probably a velocity barrier.
- Spawning Area: All Freshwater, 1960m² spawning area total.
Available only to cutthroat and rainbow trout.

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Nadzaheen		101-42-067		201-01	
Stream		Number		Geocode	
Flows SE into Nadzaheen Cove		The Todd Lakes, other small lakes and run-off.		Alpine lakes, forested / mountain slopes and some muskeg	
Location		Origin		Watershed Type	
1450m from mouth to falls		Barrier falls in		slopes.	
6/14/81 on both forks.		each creek.		Low Flow +2-3 ft

17.1ppm (5/11/71)		--		230ppm (5/11/71)	
Total Alkalinity		Total Hardness		Dissolved Solids	
				Other/Overall	
				Some flooding occurs after heavy rains.	

Spawning Area

Intertidally: 70% gravels, 15% cobble, 5% pebbles, 10% sand. South Fork: 50% angular cobble, 50% angular

Overall Stream Bottom Composition

boulders. North Fork: finer sediment occurs mixed with large gravel, Some in lower end - not a problem.
cobble, boulders and bedrock. Gravel Compaction

Hundreds of redds observed. Good to excellent quality spawning areas available, some gravels are large, but Spawning Area Available Above High Tide Mark (HTM)
chum and coho utilize them; by low-level aerial photography: 4622m² area available (3690m² estimated by conventional stream survey methods).

Excellent and abundant area exists: by low-level aerial photography technique; 12054m² total (by conventional stream survey techniques, 18,450m² was estimated).

Intertidal Spawning Area

Rearing Area Few pools in lower end of creek (mainly riffle). In No. Fork, p:r = 2:1 in braided section. -- -- -- --

Pool/Riffle Frequency (P:R Ratio)

Limited in lower section. Increases near and above fork due to LOD, overhanging vegetation, undercut banks and root wads.

Available Cover

Abundant: diptera larvae, hydropsychids (in North Fork), mayflies, caddisflies and Isopods (intertidally) observed.

Aquatic Invertebrates/Available Food Source

Intertidally: filamentous algae is abundant. Rivularia occurs on rocks above fork.

Aquatic Vegetation

Grasses and sedges in lower end. Salmonberry, currant, skunk cabbage, blueberries, mosses, apple in a cedar, hemlock and spruce canopy occur.

Terrestrial Vegetation

Up to 20% below weir due to canopy. 60% above weir due to riparian vegetation, canopy and some topography.

Shading

Abundant only near and above forks (in braided channel) - limited to under LOD and undercut banks near weir.

Extent and Quality of Rearing Area

However, it is of excellent quality. A fish passage could open up extensive rearing area in the Todd Lake system.

Reported and Suspected Use of Stream by Fish and Fishermen

Pinks, chum, coho, cutthroat, Dolly Varden and steelhead utilize this creek.

Use by Fish

Subsistence fishing, hunting, and hatchery egg takes have occurred in Nadzabeen.

Use by Fishermen

Wildlife Present

Ducks, marten, and minks observed.

Comments and Recommendations The highest recorded escapements on Annette have occurred in this major system. Excellent spawning channels, good water quality, high temperature and year-round flow help give the stream

its production characteristics (the 0+ coho fry are larger here than anywhere else). A detailed benefit: cost analysis regarding installation of fish passage over the barrier falls on the south Fork (including a more detailed stream survey above the falls) is strongly recommended.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
1959	All species	Adults	150,000	--	Largest single recorded count.
9/21/71	Pink and Chum	Adults	75,000	--	75% pinks, 25% chum

	Chum		77	373	

Additional Water Quality Data:

	Air Temp	Water Temp	pH	T.A.	T.H.	D.S.	D CO ₂	Turbidity
5/22/71	7.0C	6.0C	7.5	17.1ppm	120ppm	102.7ppm	--	--
9/1/72	17.8C	16.1C	7.0	Trace	15ppm NaCl	12.84ppm	Trace	5.0ppm due to logging activity
						Free CaCO ₃		
8/17/80		14.0C Above weir						
		17.0C Below weir						

Survey(s) and Dates Conducted

E. Biggs, C. Huntington, and J. Yuska, 6/14/81, E. Biggs, 8/19/80, and USFWS, 5/11/71.

Also examined by Tamgas Creek Hatchery Personnel and others.

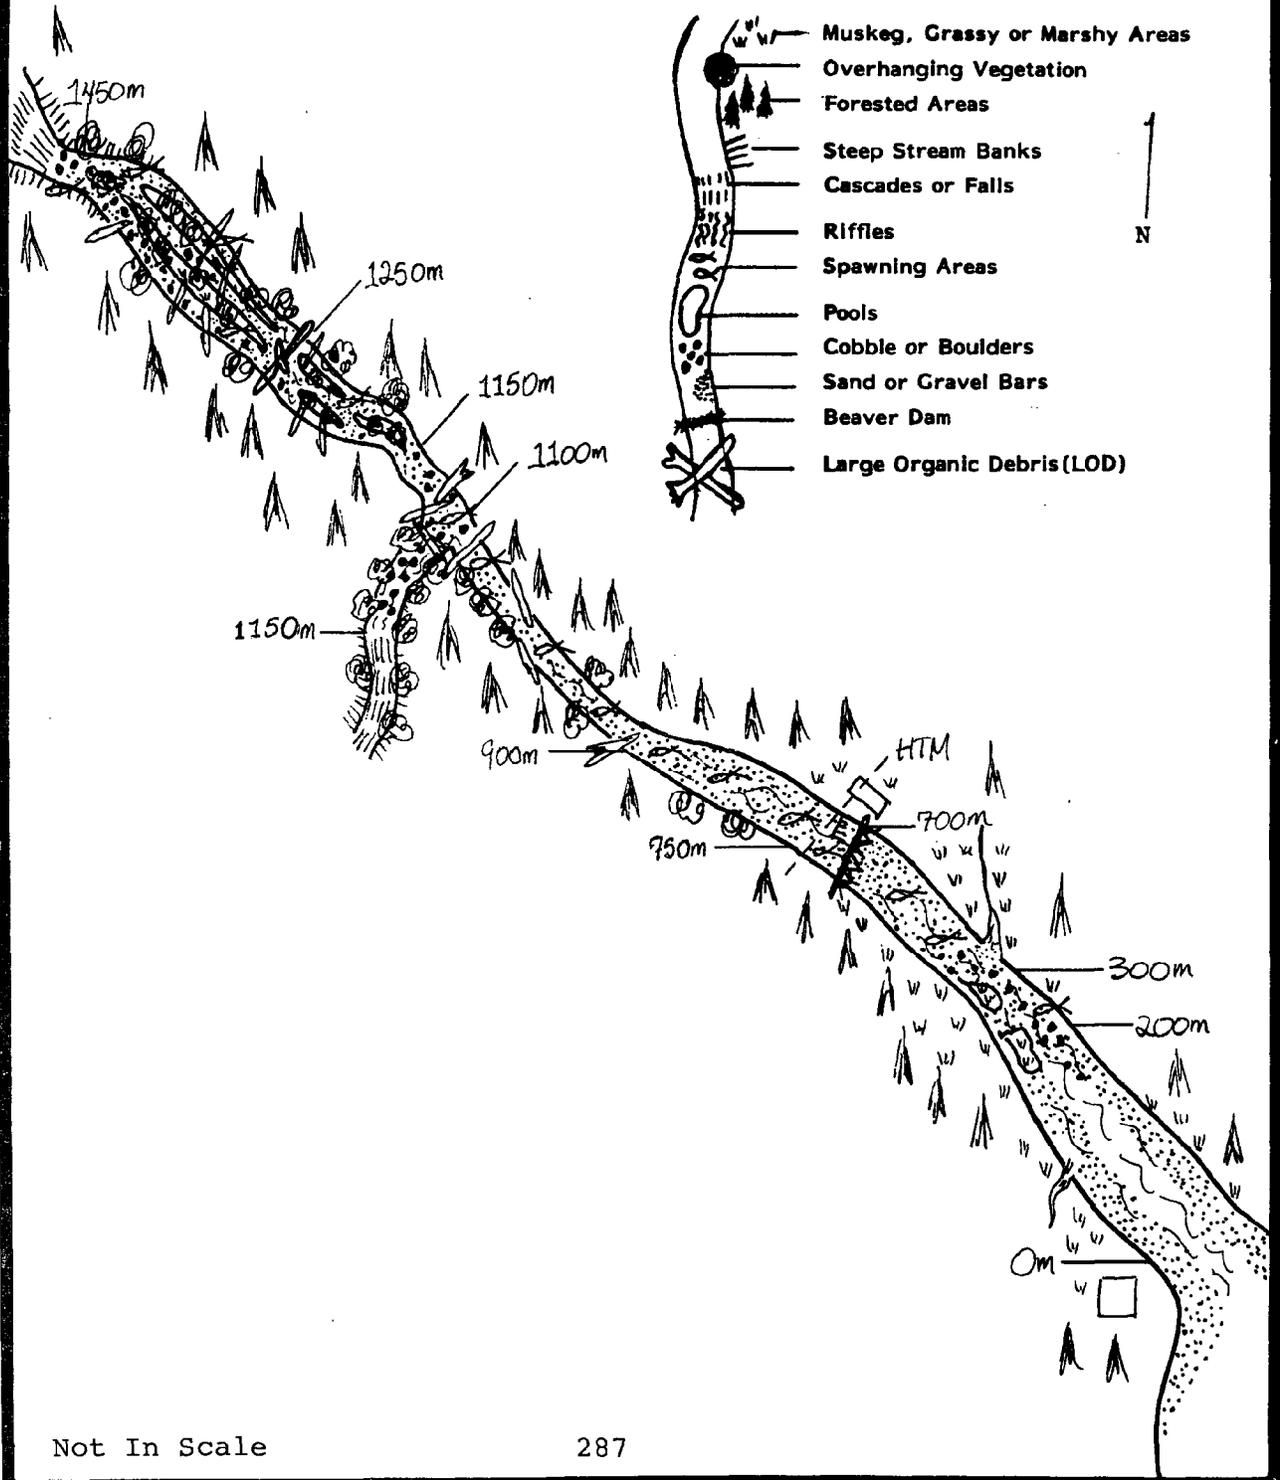

Recommended Escapement

Based on an estimate of spawning area from low-level aerial photography technique, historical escapements, and available rearing area, recommended escapements are 27,100 pink (mainly using the intertidal area), 500 chum (mainly utilizing the area above high tide) and 20 coho spawning pairs.

Potential Production Summary

A 10% overall egg-fry survival rate is used in the estimate, even though some excellent quality gravels exist. Production potential is estimated at 80,480 pinks, 2475 chum and 113 coho returning to Annette Island. Production has exceeded this in previous years and is probably due to variations in both the freshwater and marine survival rates. An enhancement study is recommended (see production potentials of tributaries to Todd Lakes).

Figure 59. NADZAHEEN CREEK (North and South Forks)

Not In Scale

NADZAHEEN CREEK (NORTH AND SOUTH FORKS)

Watershed No. 201-01
Stat. No. 101-41-067

- 0m Stream watchers cabin; insignificant tributary with a bedrock barrier flows in above cabin.
- 0-200m Bedrock, boulder and cobble riffle.
- 200-300m Average Stream Width (ASW) = 20m; spawning gravels begin at 200m, 90% usable gravels (1800m² spawning area).
- 300-700m From 0m to 700m creek flows through grassy flats: ASW = 40m, with 90% usable gravels (14,400m² spawning area). At 700m is a weir and trailer (old egg take station) with abundant coho fry in pools created by the weir.
- 700-750m ASW = 50m, 90% spawning gravels (2250m² area). Estimated High Tide Mark (HTM) at 745m.
- 750-900m ASW = 21m, ASD = .11m, 90% gravels (2835m² spawning area). Old weir occurs at 900m.
- 900-1100m ASW = 21m, 10% spawning gravels, 80% cobble, (420m² spawning area); abundant coho and trout fry observed here (trout in riffles, coho in backwater areas). Creek splits into two forks.
- 1100m-1150m (South Fork)
Boulder, cobble riffle with heavy LOD pile at mouth of fork and a set of three impassable falls at the head (1150m).
- 1100-1150m (North Fork)
ASW = 9m, ASD = .08m (5.5 cfs flow) with 50% usable gravels (160m² spawning area).
- 1150-1250m (North Fork)
Channel becomes braided with gravel bars interspaced, 10% spawning gravels.
- 1150-1450m (North Fork)
A lot of good rearing habitat available in side channels and under frequent LOD piles.
- 1450m (North Fork)
25m cascade falls over bedrock, definite barrier.

Spawning Area:

Intertidal	200-300m	1,800m ²	area	12,054m ² by Low-Level Aerial Photography

	Total	3,690m ²		

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Annette Bay Creek	102-42-068	115-01
Stream	Number	(Code) Open muskeg flats (121 acres in area).
Flows NW into Annette Bay, 600m long. Muskeg run-off		
Location	600m to end of creek	Watershed Type
6/20/81	in muskeg.	debris blockage at 75m
Date Surveyed	Section Surveyed	Moderate
--	.33 cfs / --	Stage
Ave. Gradient	Flow / Range	Flood Height
Very unstable - heavy LOD influence near beaver dam, logging and construction have caused some erosion and stream blockage - rechannelization./	Ave. Velocity/Range	--
Streambank Composition	/ Stability	Tributaries
Water Quality 8/31/72: 17.8C 14.4C 6.0 -- -- 10.0ppm 35.0ppm Above HTM 10.5C 12.0C 6.0 Clear / Slight Brown -- -- Sample Site Temp.-Air Temp.-Water Ph Clarity/Turbidity Color D.O. CO ₂ 17.1ppm (8/31/72) Resistivity=16.60 ohm/cm ³ / 4.28ppm CaCO ₃ / Siltation has occurred from logging and debris. Total Alkalinity Total Hardness Dissolved Solids Other/Overall blockage has occurred.		

Spawning Area

Below dam: 45% gravels, 25% pebbles, 20% sand, 10% silt, organic matter - trace. Muck is on bottom

Overall Stream Bottom Composition Moderate compaction with some
above dams. fines and angular gravels.

Gravel Compaction

Limited: Only about 20m² is available under the bridge and road (no area available above dams) of marginal

Spawning Area Available Above High Tide Mark (HTM)
quality - survival of eggs would be low.

Limited: only about 35m² of marginal quality area is available.

Intertidal Spawning Area

Rearing Area

Few pools - a beaver pond occurs. -- -- beaver pond is 55 x 25m

Pool/Riffle Frequency (P:R Ratio) Ave. Pool Depth/Range Ave. Pool Size/Range

In beaver pond, behind debris jam, under bridge and in a few undercut banks.

Available Cover

Sparse - caddisflies and diptera observed though.

Aquatic Invertebrates/Available Food Source

Scarce

Aquatic Vegetation

Muskeg vegetation dominates.

Terrestrial Vegetation

5% topographical (was more before logging).

Shading

Limited rearing area due to small creek size and channel instability (good cover is available).

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Only pinks could utilize creek if at all, in its present state.

Use by Fish

No fishing now - logging camp may have used creek.

Use by Fishermen

Wildlife Present

Beaver activity.

Comments and Recommendations

The channel is slowly recovering from a major disturbance. Even before disturbance, this stream (due to small size) probably did not produce large numbers of salmon. However, estuary area may be important rearing area - protect area for further development and disturbance to allow it to recover.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
8/31/72	None Seen				
6/20/81	None Seen				

Survey(s) and Dates Conducted

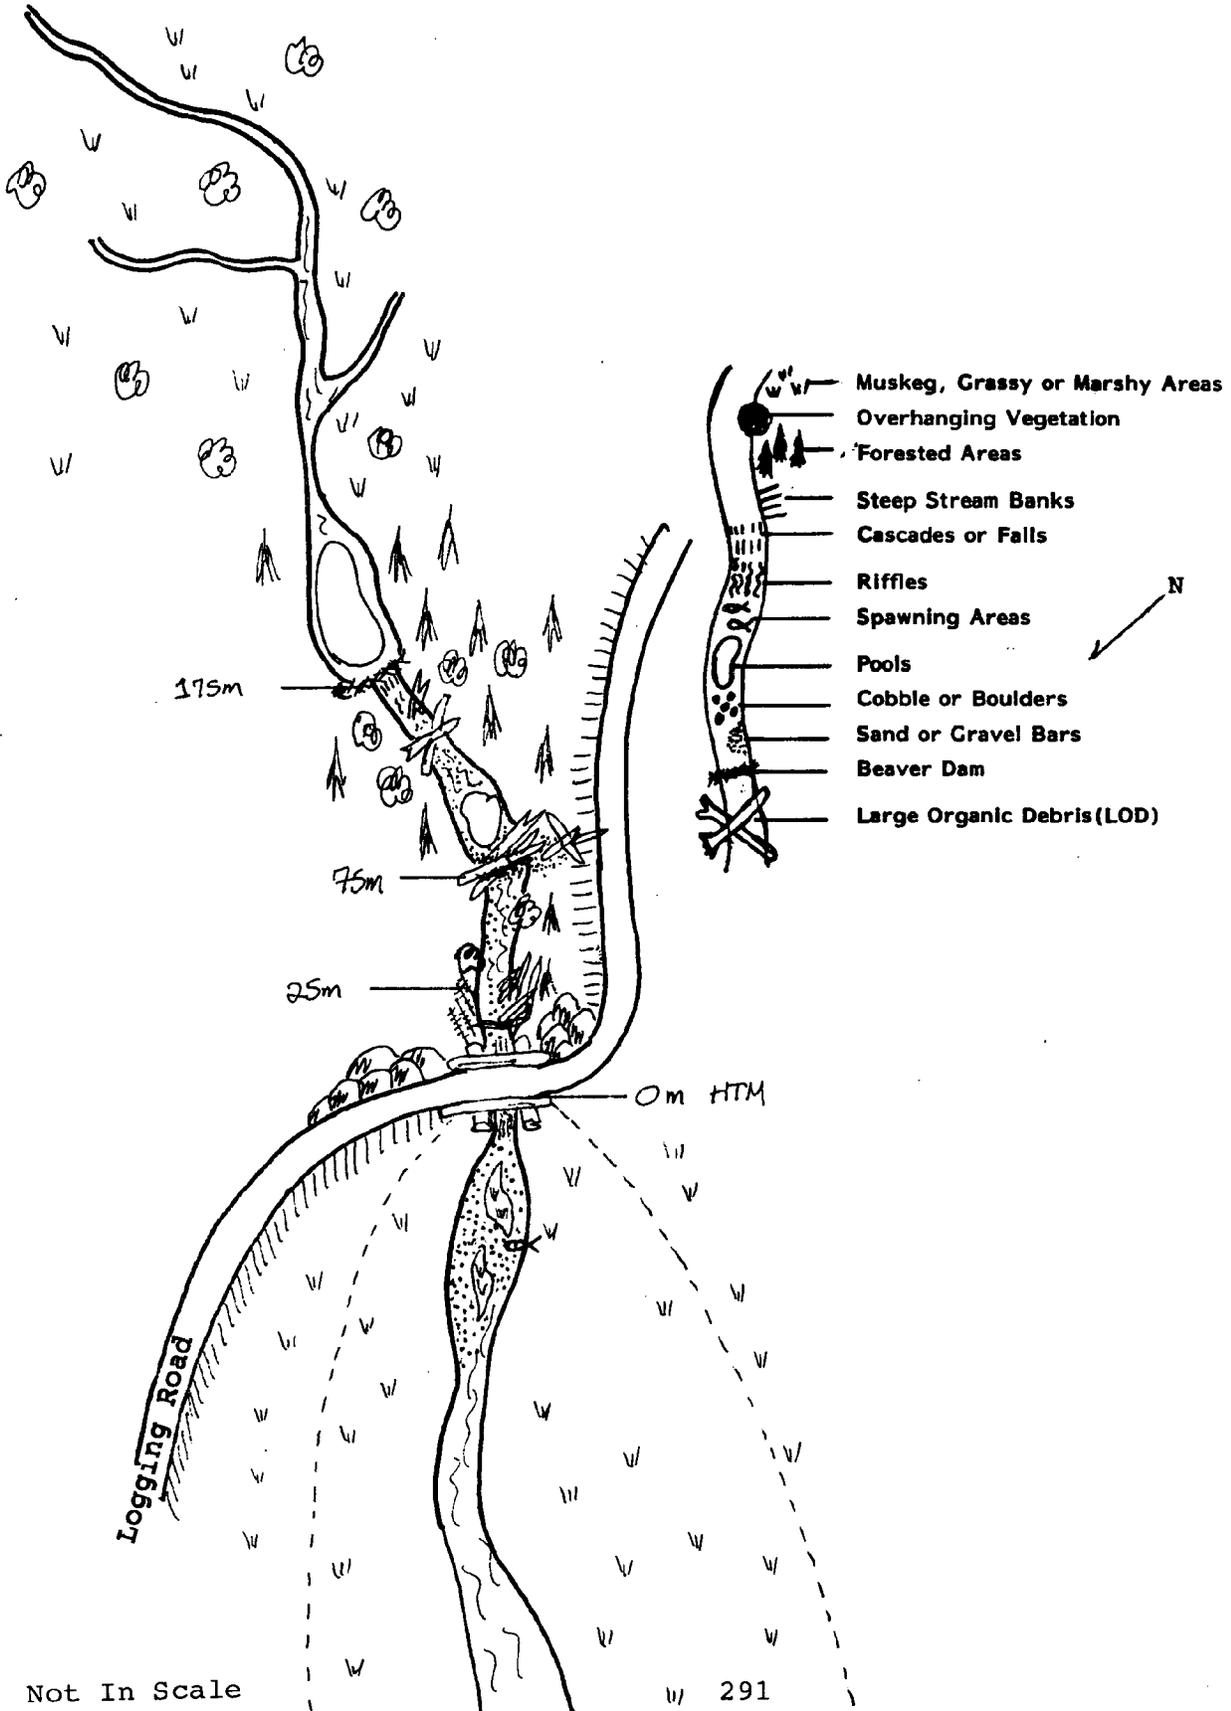

Recommended Escapement

Only 100 pink spawning pairs could utilize this creek and their success is questionable due to the fines in the gravel.

Potential Production Summary

Due to the marginal gravel quality, only about a 1.2% egg-fry survival rate is expected resulting in a production potential estimate at 36 pinks returning to Annette Island.

Figure 60. ANNETTE BAY CREEK

Not In Scale

ANNETTE BAY CREEK

Watershed No. 115-01
Stat. No. 101-42-068

Intertidal 35m² spawning area available.

0m High Tide Mark (HTM), creek flows under log bridge with 8m² available spawning area under road.

0-25m 12m² spawning area; cat tracks run into and disturb creek channel - the heavy machinery movements did cause siltation of gravels.

75m Slash and roadside debris blocking channel, no more available spawning area above 25m.

175m Beaver dam with 55 x 25m pond behind it. Above beaver dam, stream flows into muskeg flats.

Spawning Area: Limited and of marginal quality.

Intertidal 35m² area

Above HTM 20m² area

ANNETTE ISLANDS STREAM SURVEY SUMMARY

Annette Bay Halfway Creek		101-42-069	115-02
Stream		Number Mountain slope	Geocode
Flows NE into Annette Bay, 1.8 mi long./ run-off and small lakes.		Forested steep mountain slopes.	
Location	1500m above High Tide	Origin Possible barrier at 0m	Watershed Type

--	--	--	--	Looks good			
Total Alkalinity	Total Hardness	Dissolved Solids	Other/Overall				

Spawning Area

Some gravels - up to 40% in stretches; otherwise, channel is boulders, cobble, bedrock.

Overall Stream Bottom Composition

Angular with some compaction.

Gravel Compaction

710m² area is available all above the bedrock run (a possible barrier - especially for pink and chum) at

Spawning Area Available Above High Tide Mark (HTM)

150m and below 1100m in the braided channels.

None available - area is less than 5% gravels (mainly boulders and cobble).

Intertidal Spawning Area

Rearing Area

Some pools occur in braided channels

and below falls. Few riffles occur except bedrock riffles./ -- -- -- --

Pool/Riffle Frequency (P:R Ratio)	Ave. Pool Depth/Range	Ave. Pool Size/Range
-----------------------------------	-----------------------	----------------------

From some overhanging vegetation and LOD - not extensive.

Available Cover

Scarce

Aquatic Invertebrates/Available Food Source

Some filamentous algae.

Aquatic Vegetation

Azalea, grasses, skunk cabbage, a few alder, huckleberry, queens cup in cedar, hemlock and spruce.

Terrestrial Vegetation

80%, 30% due to steep banks and 40% due to vegetation, 10% due to canopy.

Shading

Not alot, but some is available in braided channels with slow flow and pools.

Extent and Quality of Rearing Area

Reported and Suspected Use of Stream by Fish and Fishermen

Pink and chum are probably blocked by the initial cascades, coho may be blocked also - none were seen.

Use by Fish

No known fishing occurs.

Use by Fishermen

Wildlife Present

None seen.

Comments and Recommendations

This stream shows potential if the fish can traverse the first 150m of the creek. A fish ladder may be a consideration, but the increase in production realized may not justify the cost.

Historical Escapement/Fish Observed

Date	Species	Size	Numbers-Live	Dead	Comments
6/21/81	None seen				

Survey(s) and Dates Conducted

J. Yuska, 6/21/81

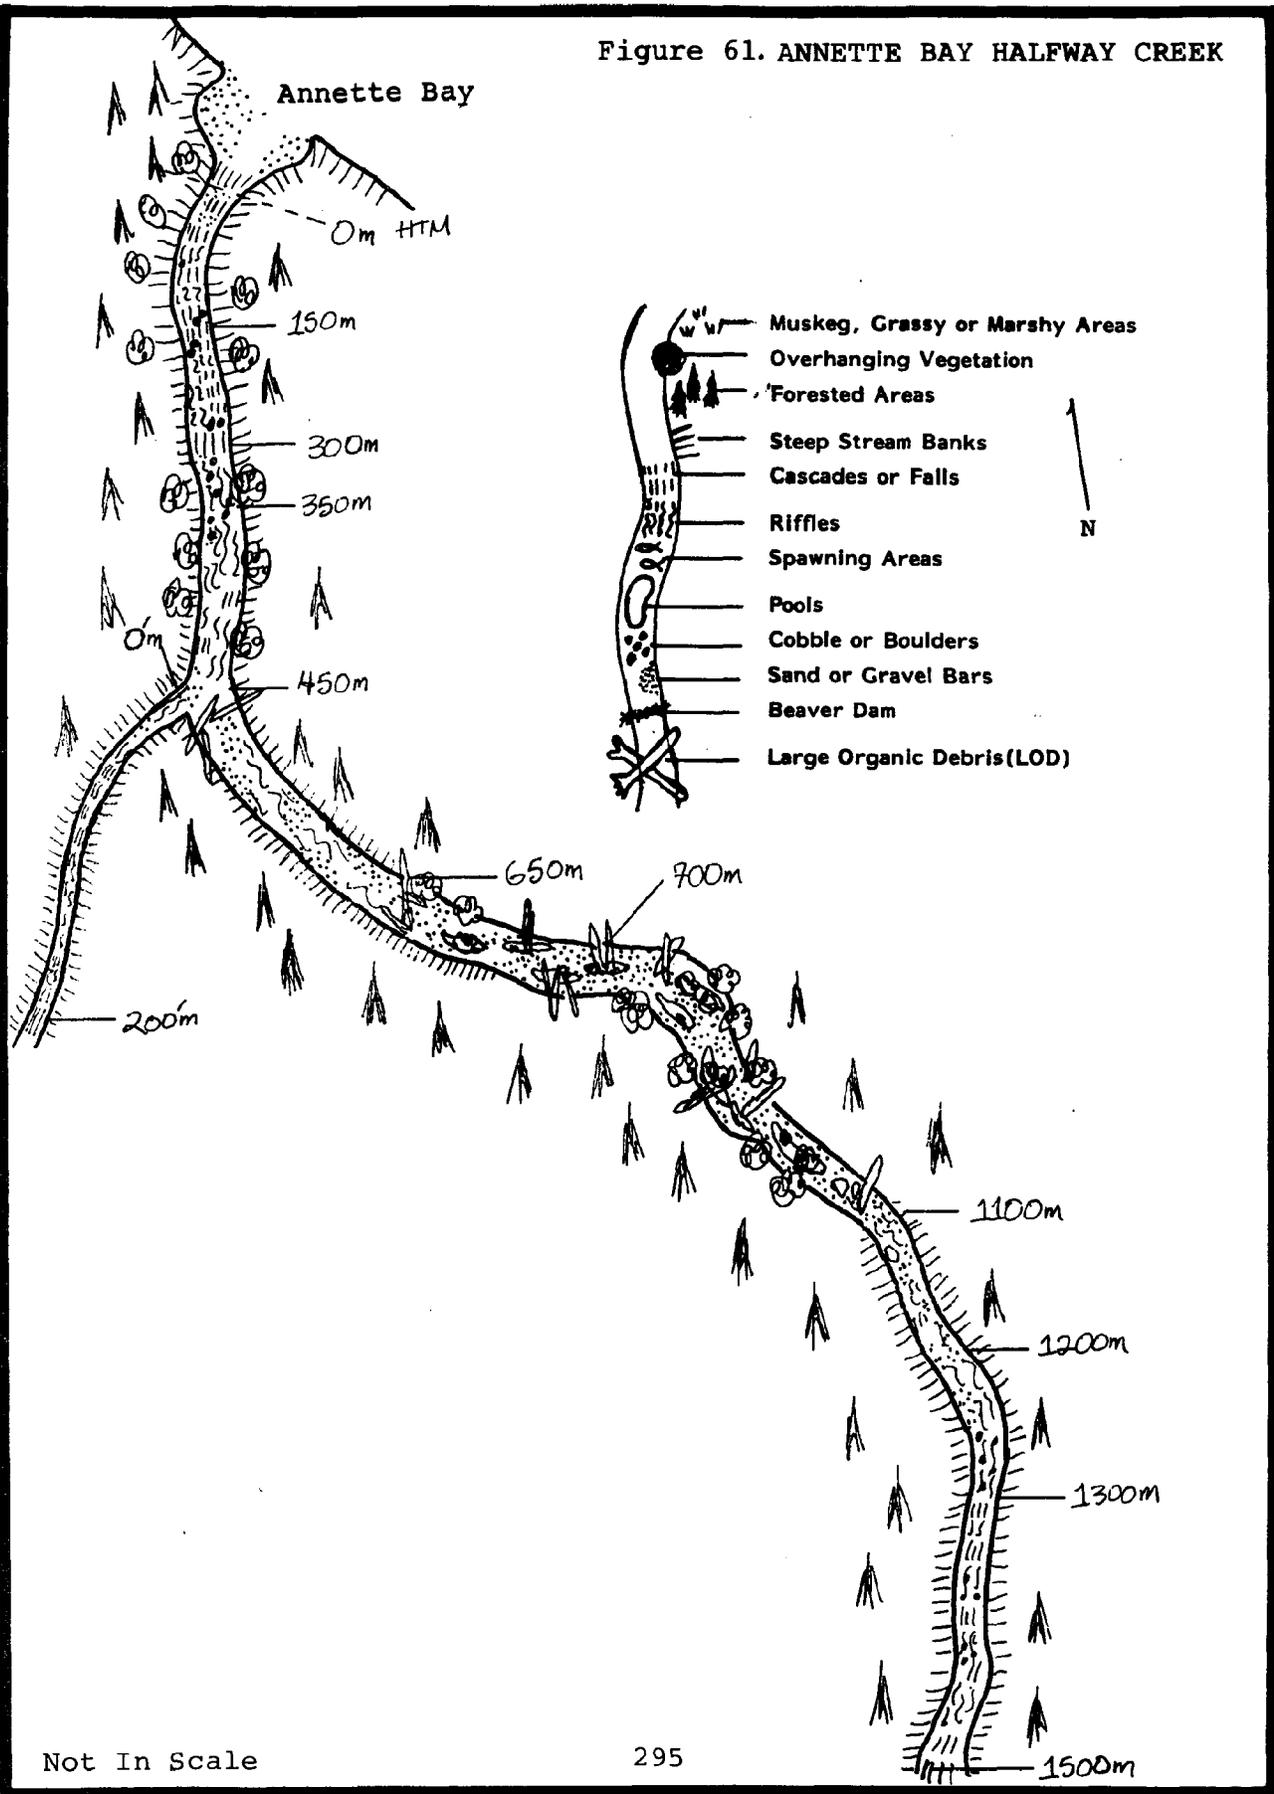

Recommended Escapement

There is enough suitable spawning area above the falls for about 1180 pink and 77 chum spawning pairs, however, it is doubtful they traverse the falls. Therefore, recommended escapement is limited to about 10 coho spawning pairs (limited by rearing area, not spawning area).

Potential Production Summary

At the above escapement, potential production is about 56 coho (assuming a 10% egg-fry survival rate).

Figure 61. ANNETTE BAY HALFWAY CREEK

Not In Scale

ANNETTE BAY HALFWAY CREEK

Watershed No. 115-02
Stat. No. 101-42-069

0m High Tide Mark (HTM) 2m falls into bay, probable barrier to pinks and chum.

0-150m All cascades and falls, probably velocity barrier, but coho may still make it.

150-300m Average Stream Width (ASW) = 3.5m, Average Stream Depth (ASD) = .25m; bottom composition is 30% cobble, 40% boulder, and 30% bedrock, gradient is lower and at 300m is a sloping falls.

350m Gradient decreases, but less than 5% gravels in bottom.

450m No rearing or spawning areas from 0m to here; tributary enters, 1.5 cfs flow and high gradient, with less than 1% gravels and a barrier falls at 200m.

450-650m ASW = 3.5m, 20% angular gravels of marginal quality (140m² spawning area).

650-1100m ASW = 3.0m, 50% gravels (540m² spawning area) with a low gradient and algae present on rocks; shading is 50% and beginning at 650m; channel braiding occurs with off-channel rearing areas and frequent LOD.

1100-1200m ASW = 3.0m, 10% gravels (30m² spawning areas); channel braiding ends and gradient increases.

1200-1300m Mainly a boulder bottom with less than 5% gravels (7m² spawning area).

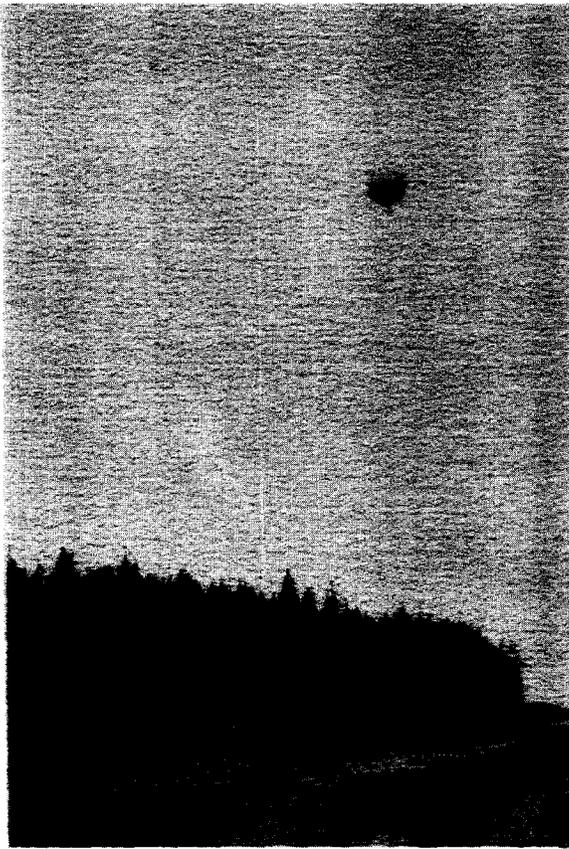

1300-1500m Gradient increases, bottom is all bedrock and boulders with no gravels.

1500m Cascades - no more available spawning or rearing habitat here or above.

Spawning Area:

Intertidal None

Above HTM May be available to coho is they can traverse initial cascades.

Appendices

APPENDIX I. GLOSSARY OF STREAM SURVEY TERMS

Angular gravels - gravels that are not rounded, but instead are irregularly shaped.

A.S.D. - average stream depth in the section surveyed or described.

A.S.W. - average stream width in the section surveyed or described.

c.f.s. - cubic feet per second; a common unit measure of streamflow.

Fork Length - the shortest measurable length of the fish, including the tail (from the tip of the snout to the middle of the tail).

f.p.s.- Feet per second; a common unit measure of stream velocity.

HTM - High Tide Mark; the level which the highest high tide reaches or high level of salt water influence.

LOD - large organic debris, e.g. dead or living logs or root wads in, over, or bordering a stream channel.

Pools - a deeper section of the creek formed by LOD, boulders, obstructions, falls, and stream currents.

Redds - a fish "nest", or the area in the gravel utilized by a salmonid in which she buries her eggs.

Riffles - a shallow section of the creek where a laminar stream flow pattern occurs.

Riparian - streamside or bordering; e.g. vegetation that borders a stream and that would not occur there if there were no stream (trees are generally not riparian).

Smolts - a juvenile salmonid that is physiologically ready for and which tends to migrate toward the ocean.

Stream Bottom Classification (USFWS)

Bedrock - solid rock

Boulder - Over 30cm in diameter

Rubble - 15-30 cm

Cobble - 10-15 cm.

Gravel - 1.25-10 cm.

Pebble - .3-1.25 cm (fines are less than .65 cm.)

Sand - less than .3 cm.

Silt - very fine - includes mud.

Organic matter - leaves, bark, wood chips (can be microscopic).

Tailout - a gravel or debris substrate pile that accumulates downstream from a pool or depression in the stream bottom, deposited by current.

APPENDIX II. METHODS AND DATA SOURCES

For a complete description of water quality measurements and sampling methods, refer to the Annette Islands Watershed Study (Pacific Rim Planners, Inc., 1979).

Most of the data measured was done so with standard equipment and by simple methods. Gradients were measured using a hand-held Sunto clinometer and distances measured by pacing them off (depths were measured with meter sticks). Streamflows were estimated by measuring cross-sectional area and multiplying by water velocity (measured using a floating object and a stop watch). Stream bottom compositions were estimated by pacing off areas of particular composition and by physically examining substrates (sampling and sifting).

Much of the other data included on the forms are straight observations and need no explanation.

Spawning area was estimated in the following ways:

1. Stream length (meters) X stream width (meters) X percentage of spawnable gravels (submerged) in that section = spawning area (square meters).
2. If spawning area is a gravel bar, the individual bars were paced off and individual areas added up for a particular stream section.

Production potential estimates were obtained by methods explained in Part 2. of this survey.

APPENDIX III. LOW LEVEL AERIAL PHOTOGRAPHY TECHNIQUE

For four of the major streams surveyed, an innovative and relatively new survey technique was utilized to measure spawning areas, rearing areas, and creek dimensions with much more accuracy and detail than the conventional mapping procedures. This method is called low level aerial photography and is carried out by use of a weather balloon with a tetrahedron frame housing a camera suspended underneath (see the Appendices cover sheet photo).

Rutzler (1979) has developed methodology for low level aerial photography of coral reefs using a 35mm camera suspended under a weather balloon. The equipment utilized in this study was an adaptation of Rutzler's system and modified to fit the requirements of stream survey work on the Olympic Peninsula in Washington and on Annette Island in Southeast Alaska by Joseph Yuska and Charles Huntington of the Department of Fisheries, Oregon State University in Corvallis, Oregon.

The 35mm camera utilized was a lightweight Olympus, OM-1 with an autowinder (motor drive) mounted on a gimballed tetrahedron (constructed of balsa wood and styrofoam) suspended from a neoprene weather balloon. The balloon was surrounded by a jacket made of extra-lightweight rip-stop nylon to protect it from protruding branches and obstructions it might have hit. Two positioning or tether lines (up to 150 feet in length), one tied to the balloon base, and one tied to the frame, were extended to the ground. A triggering cable (composed of fine telephone line wire) was extended down one of the tether lines and hooked up to the autowinder. In addition, a radio controlled shutter release was employed before the triggering cable, but found to be more difficult and less dependable to use than the wire release. A third person stood directly underneath or to one side of the balloon dragging a meter long P.V.C. pipe floating on the stream surface (to give each photo scale). The people controlling the tether lines control the height at which the balloon flies and therefore the camera focal length. The person dragging the meter pipe ensures that the camera is centered over the stream correctly.

By varying the height of the balloon over the stream which varies the camera lens focal length, and by turning the camera so that the picture frame either runs lengthwise with the stream or crosswise (to photograph the widest area possible), a wide range of stream sizes could be surveyed. To ensure that the photographs overlapped, the focal length at different heights was measured prior to flying the balloon, then the creek distance was paced off between each picture taken (the appropriate paced distance depending on balloon height). Measurements could include substrate composition of the stream, location of salmon redds, as well as detailed stream geometry and could be examined in detail in the office once the film was developed. A wide variety of films and filters could be employed to elucidate specific components of the stream system which the researcher is interested in measuring.

Low level aerial photography does not rely on cloud-free conditions and in fact, contrast in black and white photographs and detail in stream bottoms is increased on overcast days. However, the breeze must be very slight and no breeze preferable, a rare incidence and limiting factor to the use of this method in Southeast Alaska. These low level photographs could be taken below the tree canopy and could reveal much more detail than photographs taken from aircraft. In addition, this method can be done for a fraction of the cost of what aerial photographs from aircraft would cost.

Four streams were surveyed by this technique and only one set of the pictures was not utilized in spawning area estimates. The Hemlock Creek series were shot on a clear day when the reflection from the sun was so intense that the reflection off the creek surface covered up the meter-stick and prevented the interpreter from seeing the creek bottom. The other creeks shot were Kwain Creek Slough, Crab Creek Slough, and Nadzaheen and the estimates obtained from those photos are included in the individual stream survey forms.

After the photographs were developed, an enlarger was employed to standardize the size of the meter stick in each picture, compensating for the variation in the height that the balloon was flown. The photographs were then made into one composite for each creek, with sufficient overlap. The areas to be calculated could then be measured in one of three ways:

1. one could use a planimeter to measure each area of concern (a difficult task on overlapping photos)
2. one could overlay transparent graph paper, trace the creek areas of concern and then count squares or
3. one could break each creek area of concern into geometric shapes and estimate the area of each shape individually by trigonometry.

Methods 2 and 3 were utilized as 1 proved too difficult to do uniformly and accurately. By knowing the percent of spawnable gravels in each of the areas photographed, one could estimate the size of the potential spawning areas using the area estimate derived from low level aerial photography. This was done for Crab Creek Slough, Kwain Creek Slough and Nadzaheen.

The individual composites are on file at the Annette Natural Resource Center, and it is recommended that low-level aerial photography be employed in other resource inventory or environmental impact studies because of its accuracy and flexibility (in data obtained) and because of the ease at which data can be examined in the office and out of the weather.
