NOAA TECHNICAL MEMORANDA
National Weather Service, Eastern Region Subseries

The National Weather Service Eastern Region (ER) Subseries provides an informal medium for the documentation and quick dissemination of results not appropriate, or not yet ready, for formal publication. The series is used to report on work in progress, to describe technical procedures and practices, or to relate progress to a limited audience. These Technical Memoranda will report on investigations devoted primarily to regional and local problems of interest mainly to ER personnel, and hence will not be widely distributed.

Papers 1 to 22 are in the former series, ESSA Technical Memoranda, Eastern Region Technical Memoranda (ERTM); papers 23 to 37 are in the former series, ESSA Technical Memoranda, Weather Bureau Technical Memoranda (WBTM). Beginning with 38, the papers are now part of the series, NOAA Technical Memoranda NWS.

Papers 1 to 22 are available from the National Weather Service Eastern Region, Scientific Services Division, 585 Stewart Avenue, Garden City, N.Y. 11530. Beginning with 23, the papers are available from the National Technical Information Service, U.S. Department of Commerce, Sillis Bldg., 5286 Port Royal Road, Springfield, Va. 22151. Price: \$3.00 paper copy; \$0.95 microfilm. Order by accession number shown in parentheses at end of each entry.

A PROCEDURE FOR IMPROVING NATIONAL METEOROLOGICAL
CENTER OBJECTIVE PRECIPITATION FORECASTS

ABSTRACT

The National Meteorological Center's Limited-Area Fine-Mesh Model (LFM) predictions of precipitation are found to be skillful in northern New England. A technique is presented for using 12 to 24-hour LFM predictions of precipitation to modify precipitation probability forecasts prepared at the National Meteorological Center from Primitive Equation and Trajectory Model Output Statistics (PEATMOS).

INTRODUCTION

The Techniques Development Laboratory of the National Weather Service has developed a statistical method of using Primitive Equation and Trajectory Model Output Statistics (PEATMOS) for objectively determining the probability of precipitation (PoP) (1). Verification figures have shown these PEATMOS PoP forecasts to be competitive with the subjectively determined PoP forecasts formerly made at the National Meteorological Center (NMC). In January 1972, the PEATMOS PoP guidance replaced the NMC subjective PoP guidance.

The field forecaster could improve upon the PEATMOS PoP guidance forecasts if he could find some other skillful predictor of precipitation not already considered in the development of the PEATMOS PoP equations. In a number of Eastern Region Technical Attachments to the Staff Notes (2), (3), (4), it was shown that the Limited-Area Fine-Mesh Model (LFM) is skillful in predicting the occurrence of precipitation. This suggested a project to examine the feasibility of using LFM quantitative precipitation forecasts (QPF) to modify the PEATMOS PoP guidance issued from NMC.

PROCEDURE

The relative frequency of measurable precipitation ($\geq .01$ inch) was determined for cases with similar PEATMOS PoP values; for cases within a specified range of LFM QPF, and for cases with similar PEATMOS PoP values stratified further according to LFM QPF. The PEATMOS PoP and LFM QPF were obtained from facsimile maps. These forecasts were for a 12-hour period ending 24 hours after the time of initial data used to prepare the forecasts. This 12-hour period is identical to the first 12 hours covered in the public weather forecasts released near 5 a.m. and 5 p.m. local time. Forecasts and observations valid for the 12-hour night period 0000Z to 1200Z were evaluated together with forecasts and observations valid for the 12-hour day period 1200Z to 0000Z. This combining of data could mask out any diurnal effects that may exist, but a preliminary evaluation of the data indicates that diurnal variations are small.

Combined data for six stations located in New Hampshire and Maine were used to preserve geographic homogeneity and at the same time yield sufficient cases from which to arrive at conclusions. The six stations chosen were Concord, New Hampshire; and Portland, Rumford, Bangor, Eastport and Caribou, Maine.

Dependent data were initially for the period April 20, 1972, to July 31, 1972. A test was conducted on independent data for August and September 1972. All the data were then combined for the period April 20, 1972 through September 30, 1972 to arrive at a final procedure for modifying the PEATMOS PoP.

RESULTS

Table 1 presents results for the initial dependent data period of April 20, 1972 to July 31, 1972. LFM QPF and PEATMOS PoP were each independently well related to the frequency of occurrence of measurable precipitation. PEATMOS PoP without stratification for LFM QPF performed well in the low range of 0% to 30% and also in the high range of 80% or greater. In the middle range of 40% to 70%, however, the PEATMOS PoP values were too high and had poor reliability. When it forecast no precipitation, the LFM was correct in 88% of 714 cases (Table 1, bottom line). Measurable precipitation occurred in 66% of 220 cases when the LFM QPF was in the range .01 to .49 inches and, most interesting, measurable precipitation occurred in all 38 cases in which the LFM forecast .50 inches or more.

What improvement can be made to PEATMOS PoP if we consider the LFM QPF as an additional predictor? First, note in Table 1 that for all PEATMOS PoP values the frequency of precipitation increases with increasing values of LFM QPF. The PEATMOS PoP can be changed by only 10% or less when it is in the low range of 0% to 30% and the LFM QPF is equal to zero. Note that the LFM QPF is generally zero when the PEATMOS PoP is $\leq 30\%$. Little improvement is also possible for PEATMOS PoP in the high range of $\geq 50\%$ when the LFM QPF is between .01 and .49 inches. For all other combinations of PEATMOS PoP and LFM QPF, we find that the PEATMOS PoP values should be lowered when the LFM QPF is zero, should be raised when the LFM QPF is between .01 and .49 inches, and should be raised significantly to 100% when the LFM QPF is $\geq .50$ inches. The only area where the data does not support these generalizations is with PEATMOS PoP 60% and LFM QPF between .01 and .49 inches. This disagreement

is considered to be a function of the small data sample, and for a larger data sample this disagreement probably would not exist. Table 2 presents a modified PoP as a function of the original PEATMOS PoP and LFM QPF. Some subjectivity was necessary in developing Table 2 from the data presented in Table 1, especially where little or no data were available.

The modified PoP was tested and compared to unmodified PEATMOS PoP using the dependent data and then later the independent data for the months of August and September 1972 (Table 3). The results were quite good. On independent data the modified PoP had a 29% improvement in Brier score over the PEATMOS PoP and a 22% improvement over the 0.088 Brier score determined for PoP forecasts that were actually released to the public by forecasters on those days when the modified PoP was available but not necessarily referred to by the forecasters. The PoP forecasts were converted into categorical forecasts and verified (Table 3). A PoP of $\geq 50\%$ was treated as a categorical forecast of precipitation and a PoP of $\leq 40\%$ was considered as a categorical forecast of no precipitation. Regardless of the score used, the modified PoP was superior to PEATMOS PoP. For instance, the modified PoP led to categorical forecasts that were correct 10% more often than the PEATMOS PoP.

The independent data were combined with the dependent data to produce a larger data sample that could then be used to modify the results presented in Tables 1 and 2. Table 4 is the relative frequency of observed measurable precipitation as a function of PEATMOS PoP and LFM QPF for the period April 20, 1972 to September 30, 1972. Table 5 gives the modified PoPs as a function of PEATMOS PoP and LFM QPF, and is based on results presented in Table 4. The results obtained for the entire period, April 20, 1972 to September 30, 1972 (Tables 4 and 5) were not much different than the results obtained for the shorter period, April 20, 1972 to July 31, 1972 (Tables 1 and 2). Statistics in Table 6 show the skill of the unmodified PEATMOS PoP compared to the PoP modified using LFM QPF and Table 5 for the larger dependent data sample period of April 20, 1972 to September 30, 1972.

CONCLUSION

This study has developed a technique for improving precipitation forecasts by objectively using LFM 12 to 24-hour QPF to modify PEATMOS PoP. It is a pilot study which found a predictor that possessed independent information and improved upon the PEATMOS PoP. Even though the sample is small and for a particular area and season, it clearly points the way toward further studies. There is no a priori reason why this approach shouldn't show skill for other areas and seasons. The major contribution of the LFM QPF is in improving the resolution of the PEATMOS PoPs. Because numerical models and the PEATMOS PoP equations change and because the sample used in this study is small, the modified PoP should be continually verified to assure that they remain superior to the PEATMOS PoPs.

1. The first part of the document discusses the importance of maintaining accurate records of all transactions. It emphasizes that every entry should be supported by a valid receipt or invoice. This ensures transparency and allows for easy verification of the data.

2. The second section covers the process of reconciling accounts. It explains how to compare the internal records with the bank statements to identify any discrepancies. Regular reconciliation helps in catching errors early and prevents them from escalating.

3. The third part of the document addresses the issue of budgeting. It provides a framework for setting realistic financial goals and monitoring progress against them. This involves creating a detailed budget and reviewing it periodically to adjust for any changes in circumstances.

4. The final section discusses the importance of seeking professional advice when needed. It notes that while many financial tasks can be handled internally, complex situations may require the expertise of an accountant or financial advisor. Consulting with professionals can help in making informed decisions and optimizing financial performance.

Relative Frequency of Precipitation

Table 3. Comparison of skill of PEATMOS PoP and modified PoP forecasts for the dependent (April 20 - July 31, 1972) and independent (August 1 - September 30, 1972) data periods.

Definitions of scores are as follows:

Brier Score $\frac{1}{N}[\sum (F-0)^2]$ $F = \text{Forecast Probability for each case.}$
 $0 = 1 \text{ (Rain) or } 0 \text{ (No Rain) observed for}$
 each case.
 $N = \text{Total number of cases.}$

Bias $\frac{\text{Number of precipitation forecasts}}{\text{Number of precipitation cases}}$

Prefigurance Fraction of Precipitation cases correctly forecast.

Post Agreement Fraction of Precipitation forecasts which were correct.

Threat Score Fraction of "expected" and observed precipitation cases which were correctly forecast.

Percent Correct $100\% \times \frac{\text{Number of correct forecasts}}{\text{Number of forecasts}}$

Relative Frequency of Precipitation
