Science Service Meteorologist

Icicles! These natural daggers of ice are very interesting when seen sparkling in the sunlight; but look out! -- those that form over paths and entrances become a menace to life as soon as the temperature rises. Also, very slight jars caused by anyone stepping upon a porch may be just sufficient to loosen a ten-pounder. When the air temperature is below freezing, icicles form from the water of melting snow warmed by sunshine or the interior warmth of our dwellings. Icicles lose their hold as soon as the temperature rises, but often they break away due to their own weight aided by the wind or jars. It is best to knock them down rather than be knocked down by them.
