Science Service Meteorologist

Winter fogs! Everyone knows what fogs are. There is no mistaking them when encountered in their extreme dense form, cutting down as they do visibility to 1,000 feet or less. But often it is very difficult to distinguish light haze from light fog, or smoke from fog near large industrial centers. In general, fogs are ground clouds. In winter, fogs are readily formed when moist tropical air moves northward over cold surfaces of snow or land. The air and hence the contained vapor cools to the dewpoint and fog is formed. It is also formed when light ocean breezes blow inland over the cold, snow-covered land.
