Science Service Meteorologist

Water in clouds! If one is thirsty there does not seem to be much use in envying clouds -- even when they look the wettest. As a matter of fact clouds contain very little water compared with their bulk. If we leave out the water vapor in the air between the cloud droplets, it would take between 160 cubic yards (of the **densest** clouds) to 2500 cubic yards (of the lightest) to make one glass of water. In a room 15 feet square and 9 feet high, there are 80 cubic yards of space. If this were filled with the densest cloud, it would contain only one-half a glass of water -- not much for a thirsty man even if he could induce the cloud to yield every drop.
