Summer fogs! Now is the season for summer fogs where they usually occur. They form on clear, calm nights of summer along creeks, rivers, and mountain valleys. At the end of quiet, warm days, the air is full of moisture as evaporation has been going on continuously all day long from all moist surfaces. At night, and often before midnight, the surface air has cooled sufficiently by radiation that the dewpoint temperature is reached and little fog droplets are formed. These fogs are rarely very thick and are soon dissipated by the morning sun.
