The earth's variable climate! From a very remote past to the present time, the climates of the earth were not only different in different portions of the earth, but each varied from cold to warm and from warm to cold as time went on. At present we are on the warming side of a great ice age. The ice is still retreating, and only 9000 years ago it passed Stockholm, Sweden. Superimposed on these larger changes, from ice age to warmer conditions and back again, were smaller changes measured from a few years to hundreds of years, when temperatures were higher or lower than at present; or there were periods of great storminess and heavy rainfall to be succeeded again by dry periods.
