Science Service Meteorologist

Ocean temperatures! As spring advances ocean bathers look forward to the time of pleasant ocean temperature. Oceans are now cold; they are warmed almost entirely by radiations from the sun which penetrate to a considerable depth. These radiations are absorbed and turned into heat. In the summer months there will be in some seas a layer of very warm water floating over deeper colder water, while in the winter months there is a layer of cold water floating over warmer but denser water. As it takes a relatively large quantity of heat to raise the temperature of water, ocean bathing is delayed in the spring but prolonged in the fall.
