Hurricanes! To most people a storm is a storm. Storms differ from one another only in intensity. That is generally so if observations are made from only one point. But viewed as a whole the West Indian hurricanes (the season for which is just commencing) differ greatly in some details from our north temperate cyclones which travel across this continent giving us first warm and rain followed by cooler and dry weather. Some of the important differences are: hurricanes in their whole area have no great temperature change but do have very high wind speeds and torrential rains; while with our northern storms the temperatures are high in the eastern half and low in the western and wind speed much less than with hurricanes.
