Science Service Meteorologist

Salt air! It is no hallucination when one stands on the seashore and thinks he is breathing in salt mixed with the air. The air there is really salty -- strikingly so to the landsman -- because every time a wave breaks into spray some of it is evaporated, leaving tiny particles of salt to be scattered far and wide by the winds. These salt particles provide most excellent cores upon which the water vapor of the air may condense, as salt has a great affinity for water. Thus many a cloud droplet has salt for its core, which may be rained down and finally reach the ocean again.
