Science Service Meteorologist

Dust! Every housewife exclaims periodically: "where does the dust come from?" It is surprising how dust accumulates even with all windows and doors closed. The air carries around with it an enormous dust load. A little more, it is said, might create an ice age. This dust is picked up by the wind, and also comes from meteors, volcanoes and all burning material. In a large city 1000 tons of dust are deposited each year for each square mile. Dust comes into a house through cracks in windows and doors. Every time a window or door is opened, in comes another load, the occupants of a house carry some in and even add to that already in the air by kicking it up from carpets and rugs.
